4. By way of an example, the art of weaving is defined. The example shows that kingcraft has first to be separated from other kindred arts, both causal and co-operative. Nine categories are adduced which exhaust social functions. Eight are eliminated, and the ninth, the class of ministers, remains. Of these (a) slaves, (b) hirelings, (c) traders, (d) officials, (e) priests are again parted off, although the last are only with difficulty separated from the king, when (f) a strange medley of monstrous creatures come into view. Some are fierce like lions, some crafty like the fox, and some have mixed natures like centaurs and satyrs. These are the actual rulers of mankind, more sophisticated and juggling than the sophist himself. And they too must be separated from the true king.

5. The familiar tripartite distinction of monarchy, oligarchy, democracy, is doubled by introducing into each the distinction involved in the presence or absence of wealth, and in the observance or non-observance of law. But no one of the six carries in itself a scientific principle.

The true government is the rule, not of many, but of one or of a few. "And they may govern, whether poor or rich, by freewill or compulsion, and either with or without law, so long as they govern scientifically."

6. The respondent, a youthful namesake of Socrates, is shocked at the remark that the true ruler may govern without law.

This leads to a discussion of the nature of law, which is compared to the prescription left by a physician. If present, he might dispense with his own rule. So the presence of a competent ruler is better than the sovereignty of law, which makes no allowance for nature or circumstance, but tyrannically forces its own way. Imagine medicine, navigation, &c., similarly conducted by time-honoured prescription, with penalties for innovation;—what would become of civilization? Yet if law is disregarded by rulers who are unscientific and warped by self-interest, this leads to far worse evils. For the laws are based on some experience and wisdom. Hence, in the continued absence of the true ruler, the best course, though only second best, is the strict observance of law. And he who so rules in humble imitation of the scientific governor may be truly called a king, although if the divine lawgiver were to appear his living will would supersede the law.

7. As it is, though cities survive many evils, yet many are shipwrecked because of the ignorance of those at the helm. The order of badness in the actual states is—

1. Constitutional monarchy.
2. Constitutional oligarchy.
3. Law-abiding democracy.
4. Law-breaking democracy.
5. Law-defying oligarchy.
6. Tyranny.

—4. It remains to separate from the true ruler those who co-operate him as subordinates, the general, the judge, the orator. His

own peculiar function is an art of weaving strength (the warp) with gentleness (the woof), when education has prepared them,—and this (1) by administration, (2) by marriage.

The four preceding dialogues have shown (1) the gradual transformation of the Platonic ideas (while still objective) into forms of thought, (2) the tendency to group them into series of categories, (3) a corresponding advance in psychological classification, (4) an increasing importance given to method, (5) the inclination to inquire into processes (γενέσεις) as well as into the nature of being.

Meanwhile Plato's approach to the Eleatics, though in the way of criticism, has brought into prominence the notions of unity, being, sameness, difference, and has left somewhat in abeyance the idea of good. To this "highest of *Philebus* all studies" Plato now returns, equipped with his improved instruments, and ready to forge new ones in the same laboratory, or in some other, should occasion serve. His converse with Parmenides ended in his assertion of an element of difference pervading all things, in other words, of an indeterminate element underlying all determinations. This brings him again into relation with the Pythagoreans, who had similarly asserted the combination of finite and infinite in the universe.

Taking advantage of their help, he gains a more advanced (but still ideal) conception of the concrete harmony of things, and approaches the definition of that which in the *Republic* he but shadowed forth.

With this most serious inquiry there is combined (as in the *Sophistes* and *Politicus*) an ironical and controversial use of dialectic, by which the juggler and false pretender (who is in this case the goddess of pleasure), after claiming the highest place, is thrust down to the lowest.

It must be admitted that the style of the *Philebus* is far from brilliant, or even clear. In the effort of connecting abstractions Plato's movement is more laboured than in his first glad realization of them.

Instead of attempting here to follow the windings of the dialogue, it must suffice to state the main result. Neither pleasure nor knowledge is the highest good, and the good eludes definition; but the shrine, or habitation, of the good is a complex life of which the elements are, in order of merit—(1) measure, the cause of all right mixture; (2) (a) beauty, the effect, and (b) reality, the inseparable condition; (3) intellect; (4) science, art, and right opinion; (5) pure pleasure unaccompanied with pain. "Not all the animal kingdom shall induce us to put pleasure first."

The *Philebus* introduces us to the interior of the Academy in the lifetime of the master. More than any other of the dialogues it recalls Aristotle's description of Plato's teaching. But, while his followers seem early to have fallen under the dominance of the latest phase of his doctrine, Plato himself, even in the *Philebus*, is still detached from any servitude to the creations of his own mind. He manipulates them as the medium for expressing his fresh thoughts, but they are not yet crystallized into a system.

"I will remind you," Socrates, "of what has been omitted," says *Protarchus* at the conclusion of this dialogue. The last (presumably) of Plato's metaphysical writings thus fitly ends with a confession of incompleteness. But if, as M. Renan says, "the most fatal error is to believe that one serves one's country by calumniating those who founded it," neither is it for the interest of science to ignore these imperfect anticipations. By methods elaborated in the course of centuries, and far more sure than any which Plato had at his command, mankind have gained an extent of knowledge which he dreamt not of.<sup>1</sup> But the Greek metaphysician is none the

<sup>1</sup> See, however, *Polit.*, 272 C, D

less a pioneer of knowledge,<sup>1</sup> while the special sciences of ethics and psychology had been carried from infancy to adolescence in a single lifetime.

The imaginative dialogues.

VII. *Timæus*, *Critias*, [*Hermocrates*].—As the *Sophistes* and *Politicus* were written in continuation of the *Theætetus*, so, at some uncertain time, Plato conceived the design of writing a great trilogy, for which the ideal state depicted in the *Republic* should be the point of departure. The grand outline there sketched by Socrates was now to be filled up by Critias and Hermocrates. The form set up by reasoning should be made alive, the "airy burghers" should be seen "making history." As a prelude to this magnificent celebration, Timæus, the Pythagorean philosopher, who is present at the Panathenæa, is invited to discourse of the origin of all things, and to bring down the glorious theme to the creation of man. What should have followed this, but is only commenced in the fragment of the *Critias*, would have been the story, not of a fall, but of the triumph of reason in humanity.

In the *Philebus* (59 A, comp. 62 D) Plato speaks with a touch of contempt of the life-long investigation of nature, as being concerned only with this visible universe, and immersed in the study of phenomena, whether past, present, or to come, which admit of no stability and therefore of no certainty. "These things have no absolute first principle, and can never be the objects of reason and true science."

Yet even this lower knowledge is there admitted as an element of that life which is the habitation of the good. And there are not wanting signs in his later dialogues that Plato's imagination had again been strongly drawn towards those physical studies which, as the *Phædo* shows, had fascinated him in youth. That nature and the world proceed "according to God and not according to chance" is the belief of the Eleatic stranger, to which he perceives that Theætetus will be irresistibly drawn as he grows older. In the midst of dialectical abstractions, the processes of actual production (*γενέσις*) have been increasingly borne in mind. And the myth in the *Politicus* turns on cosmological conceptions which, although differing from those in the *Timæus*, and more accordant with Plato's bitterest mood, yet throw a new light on the deeper current of his thoughts. In the same passage (272 C) there occurs the first clear anticipation of an *interrogatio naturæ*.

The impulse in this new direction, if not originated, was manifestly reinforced, through closer intercourse with the Pythagorean school. And the choice of Timæus the Pythagorean as chief speaker is an acknowledgment of this obvious tendency. If in the course of the dialogue there occur ideas apparently borrowed from the Atomists, whom Plato persistently ignored, this fact ought probably to be referred to some early reaction of Atomic on Pythagorean doctrine. It is important to observe, however, that not only the *Timæus*, but the unfinished whole of which it forms the introduction, is professedly an imaginative creation. For the legend of prehistoric Athens and of Atlantis, whereof Critias was to relate what belonged to internal policy and Hermocrates the conduct of the war, would have been no other than a prose poem, a "mythological lie," conceived in the spirit of the *Republic*, and in the form of a fictitious narrative. And, therefore, when Timæus professes to give only a probable account of shadowy truths, he must be taken at his word, and not criticized in too exacting a spirit. His descriptions have much the same relation to the natural philosophy of Plato's time that Milton's cosmology has to the serious investigations of Galileo or Copernicus,—except that all physical

speculation hitherto partook in some measure of this half-mythological character, and that Plato's mind, although working in an unfamiliar region, is still that of a speculative philosopher.

As Parmenides, after demonstrating the nonentity of growth and decay, was yet impelled to give some account of this non-existent and unintelligible phenomenal world, so Plato, although warned off by Socrates, must needs attempt to give a probable and comprehensive description of the visible universe and its creation. In doing so he acknowledges an imperfect truth in theories which his dialectic had previously set aside. In examining the earlier philosophers he has already transgressed the limits prescribed by Socrates, and the effort to connect ideas has made him more and more conscious of the gap between the ideal and the actual. He cannot rest until he has done his utmost to fill up the chasm—calling in the help of imagination where reason fails him.

His dominant thought is still that of a deduction from the "reason of the best," as in the *Phædo*, or "the idea of good," as in the *Republic*. But both his abstract idealism and his absolute optimism were by this time considerably modified, and, although not confounding "causes with conditions," as he once accused Anaxagoras of doing, he yet assigns more scope to "second causes" than he would then have been willing to attribute to them. This partly comes of ripening experience and a deepening sense of the persistency of evil, and partly from the feeling—which seems to have grown upon him in later life—of the distance between God and man.

Timæus begins by assuming (1) that the universe being corporeal is caused and had a beginning, and (2) that its mysterious author made it after an everlasting pattern. Yet, being bodily and visible, it can only be made the subject, humanly speaking, of probable discourse.

Thus much being premised, he proceeds to unfold—(A) the work of mind in creation, (B) the effects of necessity, including the general and specific attributes of bodies, (C) the principles of physiology, and (D) an outline of pathology and medicine.

To give a full account of such a comprehensive treatise is beyond the scope of this article, and the *Timæus*, however great and interesting, has been well described as an out-building of the great fabric of original Platonism. A very few scattered observations are all that there is space for here.

(A) 1. In the mythology of the *Timæus* some of the conceptions which attained logical clearness in the *Sophist* and *Philebus* resume an ontological form. Thus, in compounding the soul-stuff of the universe, the father of all takes of the continuous and discrete and fuses them into an essence (the composite being of the *Philebus*). Again he takes of the same and other (comp. the *Sophist*), overcoming their inherent repugnance by his sovereign act.

2. The notion of an economy or reservation in Plato has been often exaggerated and misapplied. But it is difficult to acquit him of intentional obscurity in speaking of the creation of the Earth. It is clear, though Plato does not say so, that she is meant to have been created together with the Heaven and together with Time, and so before the other "gods within the heaven," i.e., the sun and moon and five planets, and it is a plausible supposition that she is the "artificer of day and night" by interposing her bulk to the sun's rays. If the word *εἰλωμένη* in p. 40 implies motion (as Aristotle thought<sup>2</sup>), it cannot be, as Grote supposed, a motion contemporaneous with that of the outer sphere, but either some far slower motion, perhaps assumed in order to account for the shifting of the seasons, or an equal retrograde motion which is supposed to neutralize in her case the "motion of the same." She clings to the centre, as her natural abode. And the diurnal motion of the heavens is due not to any mechanical force but to the soul of the world extending from the centre to the poles and comprehending all.

3. Immortality is in the *Timæus* dependent on the will of the Eternal. And the sublime idea of eternity is here first formulated.

4. The phenomena of vision and hearing are included among the works of reason, because the final cause of these higher senses is to give men perception of number, through contemplation of the measures of time.

(B) 1. It has been commonly said that the four elements of the *Timæus* are geometrical figures, without content. This is not true. For what purpose does Plato introduce, "besides the archetype and

<sup>1</sup> See Jowett, *Introd. to the Timæus*.

<sup>2</sup> Aristotle, however, uses *εἰλωμένη*, a different word.

the created form, a third kind, dim and hard to conceive, a sort of limbo or matrix of creation," if not to fill up the triangles which are elements of elements, and to be the vehicle of the forms compounded of them? It has been supposed that this "nurse of generation" is identical with "space," and it cannot be said that they are clearly kept apart by Plato. But he had a distinct nomenclature for either, and, although gravity is explained away (so that his molecules, unlike Clerk Maxwell's, may be called imponderable), yet extension, or the property of filling space, is sufficiently implied.

2. The difference of size in the triangles and varying sharpness of their outlines are ingenious though inadequate expedients, adopted in order to account for qualitative difference and physical change.

3. In criticizing the illusory notion of up and down Plato broaches the conception of antipodes.

4. More distinctly than in the *Philebus*, bodily pleasure is explained by "a sudden and sensible return to nature" (comp. *Ar., Rhét.*, i. 11, § 1; *N. E.*, vii. 10).

5. Natural philosophers are warned against experimenting on the mixture of colours, which is a divine process and forbidden to man.

(C) 1. Plato tends more and more in his later writings to account for moral evil by physical conditions, thus arriving at the Socratic principle of the involuntariness of vice by a different road.

Hence in the *Timæus* not the body only is made by the inferior gods, but they also create the lower and mortal parts of the human soul:—the principle of anger which is planted in the breast, within hearing of reason, and that of appetite which is lodged below the diaphragm like an animal tied in a stall, with the stomach for a crib and the liver for a "soothsaying" looking-glass to soothe or terrify it when tempted to break loose.

2. The brain-pan was left bare of protecting flesh "because the sons of God who framed us deliberately chose for us a precarious life with capability of reason, in preference to a long secure existence with obstruction of thought."

3. The nails are a rudimentary provision for the lower animals, into which degenerate souls were afterwards to be transformed.

4. Vegetables have sensation but not motion.

5. By way of illustrating the very curious account here given of respiration, it is asserted that what is commonly thought to be the attraction of the magnet is really due to rotatory motion and displacement.

6. When the original particles wear out, and the bonds of soul and body in the marrow give way, the soul escapes delightedly and flies away. This is the painless death of natural decay.

(D) 1. The dependence of mental disease on bodily conditions is more fully recognized in the *Timæus* than elsewhere in Plato (contrast the *Charmides*, for example).

2. He has also changed his mind about the treatment of disease, and shows more respect for regimen and diet than in the *Republic*. Diseases are a kind of second nature, and should be treated accordingly.

3. It is also a remark in contrast with the *Republic*, that over-study leads to head complications, which physicians ascribe to chill and find intractable.

Lastly, it is one of the strange irregularities in the composition of the *Timæus* that the creation of woman and the relation of the sexes<sup>1</sup> to each other are subjects reserved to the end, because this is the place given to the lower animals, and woman (compare the *Phaedrus*) is the first transmigration from the form of man. This order is probably not to be attributed to Plato's own thought, but to some peculiarity of Pythagorean or Orphic tradition.

VIII. *The Laws*.—The two series of dialogues, the dialectical and the imaginative,—*Sophistes*, *Politicus*, *Philosophus*,—*Timæus*, *Critias*, *Hermocrates*,—were left incomplete. For Plato had concentrated his declining powers, in the evening of his life,<sup>2</sup> upon a different task. He was resolved to leave behind him, if he could so far overcome the infirmities of age,<sup>3</sup> a code of laws, conceived in a spirit of concession, and such as he still hoped that some Hellenic state might sanction. The motive for this great work may be gathered from the *Politicus*. The physician in departing is to give a written prescription, adapted as far as possible to the condition of those from whom he goes away. This is the second-best course, in the absence of the philosopher-king. And, as the Hellenic world will not listen to Plato's heroic remedy, he accom-

modates his counsel to their preconceptions. He returns *Laws*, once more from abstract discussions to study the application of ideas to life, and though, by the conditions of the problem, his course is "nearer earth and less in light," this long writing, which is said to have been posthumous,<sup>4</sup> has a peculiar interest. The ripeness of accumulated experience and the mellowness of wise contemplation make up for the loss of prophetic insight and poetic charm.

The form of dialogue is still retained, and an aged Athenian is imagined as discoursing of legislation with the Lacedæmonian Megillus and the Cretan Clinias, who has in view the foundation of a new colony, and is on his way with his two companions from Cnossus to the temple and oracle of Zeus.

Plato now aims at moderating between Dorian and Ionian law, freely criticizing both, and refining on them from a higher point of view. "The praise of obedience, the authority assigned to elders, the prohibition of dowries, the enforcement of marriage, the common meals, the distribution and inalienability of land, the institution of the Crypteia, the freedom of bequest to a favourite son, the dislike of city walls—all reflect the custom of Sparta."

... "The use of the lot, the scrutiny of magistrates, the monthly courses of the council, the pardon of the forgiven homicide, most of the regulations about testaments and the guardianship of orphans, the degrees of consanguinity recognized by law, correspond to Athenian laws and customs" (Jowett).

The philosopher's own thoughts come out most strongly in the "preludes" to the laws,<sup>5</sup> and in the regulations concerning education, marriage, and the punishment of impiety (*i.e.*, 1st, atheism, 2d, denial of providence, 3d and worst, immoral superstition). The difficulty which is met in the *Politicus* by the abandonment of the world for a time, and in the *Timæus* by the lieutenantancy of lower gods, here leads to the hypothesis of an evil soul. The priority of mind (often before asserted) and the increased importance attached to numbers are the chief indications of Plato's latest thoughts about the intelligible world. But it must be remembered that the higher education (answering to *Rep.*, vi., vii.) is expressly reserved.<sup>6</sup> Had Plato written his own *Epinomis*, the proportions of the whole work (not then "acephalous") might have been vastly changed.

The severity of the penalties attached to the three forms of heresy, especially to the third and worst of them, has led to the remark that Plato, after asserting "liberty of prophesying," had become intolerant and bigoted in his old age. But the idea of toleration in the modern sense was never distinctly present to the mind of any ancient philosopher. And, if in the *Laws* the lines of thought have in one way hardened, there are other ways in which experience has softened them. Plato's "second-best" constitution contains a provision, which was not admissible in the "perfect state," for possible changes and readaptations in the future. The power of self-reformation is hedged round indeed with extreme precautions; and no young or middle-aged citizen is ever to hear a word said in depreciation of any jot or tittle of the existing law. But that it should be provided, however guardedly, that select commissioners, after travelling far and wide, should bring back of the fruit of their observations for the consideration of the nocturnal council, and that a power of constitutionally

amending the laws should thus be admitted into the state, is sufficiently remarkable, when the would-be finality of ancient legislation is considered. Plato even comes near to the reflexion that "constitutions are not made, but grow" (iv. 709 A).

Plato in the *Laws* desists finally from impersonating Socrates. But he is in some ways nearer to his master in spirit than when he composed the *Phædrus*. The sympathy with common life, the acceptance of Greek religion, the deepening humanity, are no less essentially Socratic than the love of truth which breathes in every page. And some particular aspects of Socratism reappear, such as the question about courage<sup>1</sup> and that concerning the unity of virtue.<sup>2</sup>

Doubtful  
and spu-  
rious  
works.

Of the dialogues forming part of the "Platonic canon," and not included in the preceding survey, the *Lesser Hippias*, *First Alcibiades*, and *Menæxenus* are the most Platonic, though probably not Plato's. The *Greater Hippias* and the *Clitophon* are also admitted to have some plausibility. The *Second Alcibiades* (on Prayer), the *Hipparchus* (touching on Pisistratus and Homer), *Minos* ("de lege"), *Epinomis*, *Erastus*, *Theages*, are generally condemned, though most of them are very early forgeries or Academic exercises.<sup>3</sup> And the *Axiochus* (though sometimes prized for its subject, "the contempt of death"), the *De Justo*, *De Virtute*, *Demodocus*, *Sisyphus*, *Eryxias* (a not-uninteresting treatise on the use of money), together with the so-called *Definitions*, were rejected in ancient times, and are marked as spurious in the MSS.

Two great forces are persistent in Plato, the love of truth and zeal for human improvement. In the period culminating with the *Republic*, these two motives, the speculative and the practical, are fused in one harmonious working. In the succeeding period, without excluding one another, they operate with alternate intensity. In the varied outcome of his long literary career, the metaphysical "doctrine of ideas" which has been associated with Plato's name underwent many important changes. But pervading all of these there is the same constant belief in the supremacy of reason and the identity of truth and good. From that abiding root spring forth a multitude of thoughts concerning the mind and human things,—turning chiefly on the principles of psychology, education, and political reform,—thoughts which, although unverified, and often needing correction from experience, still constitute Plato the most fruitful of philo-sophical writers. While general ideas are powerful for good or ill, while abstractions are necessary to science, while mankind are apt to crave after perfection, and ideals, either in art or life, have an acknowledged value, so long the renown of Plato will continue. "All philosophic truth is Plato rightly divined; all philo-sophic error is Plato misunderstood"—is the verdict of one of the keenest of modern metaphysicians.<sup>4</sup>

Plato's followers, however, have seldom kept the proportions of his teaching. The diverse elements of his doctrine have survived the spirit that informed them. The Pythagorizing mysticism of the *Timæus* has been more prized than the subtle and clear thinking of the *Theætetus*. Logical inquiries have been hardened into a barren ontology. Semi-mythical statements have been construed literally, and mystic fancies perpetuated without the genuine thought which underlay them. A part (and not the essential part) of his philosophy has been treated as the whole. But the influence of Plato has extended far beyond the limits of the Platonic schools. The debt of

Aristotle to his master has never yet been fully estimated. Zeno, Chrysippus, Epicurus borrowed from Plato more than they knew. The moral ideal of Plutarch and that of the Roman Stoics, which have both so deeply affected the modern world, could not have existed without him. Neopythagoreanism was really a crude Neoplatonism. And the Sceptics availed themselves of weapons either forged by Plato or borrowed by him from the Sophists. A wholly distinct line of infiltration is suggested by the mention of Philo and the Alexandrian schools, and of Clement and Origen, while Gnostic heresies and even Talmudic mysticism betray perversions of the same influence. The effect of Hellenic thought on Christian theology and on the life of Christendom is a subject for a volume, and has been pointed out in part by Professor E. Zeller and others (comp. NEOPLATONISM). Yet when Plotinus in the 3d century (after hearing Ammonius), amidst the revival of religious paganism, founded a new spiritualistic philosophy upon the study of Plato and Aristotle combined, this return to the fountain-head had all the effect of novelty. And for more than two centuries, from Plotinus to Proclus, the great effort to base life anew on the Platonic wisdom was continued. But it was rather the ghost than the spirit of Plato that was so "unsphered." Instead of striving to reform the world, the Neoplatonist sought after a retired and cloistered virtue. Instead of vitalizing science with fresh thought, he lost hold of all reality in the contemplation of infinite unity. He had some skill in dealing with abstractions, but laid a feeble hold upon the actual world.

"Hermes Trismegistus" and "Dionysius Areopagita" are names that mark the continuation of this influence into the Middle Ages. The pseudo-Dionysius was translated by Erigena in the 9th century.

Two more "Platonic" revivals have to be recorded,—at Florence in the 15th and at Cambridge in the 17th century. Both were enthusiastic and both uncritical. The translation of the dialogues into Latin by Marsiglio Ficino was the most lasting effect of the former movement, which was tinged with the unscientific ardour of the Renaissance. The preference still accorded to the *Timæus* is a fair indication of the tendency to bring *fumum et fulgore* which probably marred the discussions of the Florentine Academy concerning the "chief good." The new humanism had also a sentimental cast, which was alien from Plato. Yet the effect of this spirit on art and literature was very great, and may be clearly traced not only in Italian but in English poetry.

"The Cambridge Platonists" have been described by Principal Tulloch in his important work on *Rational Theology in England in the 17th Century*. Their views were mainly due to a reaction from the philosophy of Hobbes, and were at first suggested as much by Plotinus as by Plato. It is curious to find that, just as Socrates and Ammonius (the teacher of Plotinus) left no writings, so Whiehote, the founder of this school, worked chiefly through conversation and preaching. His pupils exercised a considerable influence for good, especially on English theology; and in aspiration if not in thought they derived something from Plato, but they seem to have been incapable of separating his meaning from that of his interpreters, and Cudworth, their most consistent writer, was at once more systematic and less scientific than the Athenian philosopher. The translations of Sydenham and Taylor in the 18th century and the beginning of the 19th are proofs of the continued influence of Platonism in England.

The critical study of Plato begins from Schleiermacher, who did good work as an interpreter, and tried to arrange the dialogues in the order of composition. His attempt, which, like many efforts of constructive criticism, went far

<sup>1</sup> Comp. *Laches*.

<sup>2</sup> Comp. *Protagoras*.

<sup>3</sup> According to Schaarschmidt, only nine dialogues are genuine,—*Protag.*, *Phædr.*, *Symp.*, *Apol.*, *Crito*, *Phædo*, *Rep.*, *Tim.*, *Leges*.

<sup>4</sup> Ferrier, *Institutes of Metaphysics*, p. 169 (sect. I., prop. vi. § 12).

beyond possibility, was vitiated by the ground-fallacy of supposing that Plato had from the first a complete system in his mind which he partially and gradually revealed in writing. At a considerably later time Karl Friedrich Hermann, to whom all students of Plato are indebted, renewed the same endeavour on the far more plausible assumption that the dialogues faithfully reflect the growth of Plato's mind. But he also was too sanguine, and exaggerated the possibility of tracing a connexion between the outward events of Plato's life and the progress of his thoughts. This great question of the order of the dialogues, which has been debated by numberless writers, is one which only admits of an approximate solution. Much confusion, however, has been obviated by the hypothesis (first hinted at by Ueberweg, and since supported by the present writer and others) that the *Sophistes* and *Politicus*, whose genuineness had been called in question by Socher, are really intermediate between the *Republic* and the *Laws*. The allocation of these dialogues, and consequently of the *Philebus*, not only on grounds of metaphysical criticism, but also on philological and other evidence of a more tangible kind, supplies a point of view from which it becomes possible to trace with confidence the general outlines of Plato's literary and philosophical development. Reflecting at first in various aspects the impressions received from Socrates, he is gradually touched with an inspiration which becomes his own, and which seeks utterance in half-poetical forms. Then first the ethical and by and by the metaphysical interest becomes predominant. And for a while this last is all absorbing, as he confronts the central problems which his own thoughts have raised. But, again, the hard-won acquisitions of this dialectical movement must be fused anew with imagination and applied to life. And in a final effort to use his intellectual wealth for the subvention of human need the great spirit passed away.

Campbell (1867); *Phædrus*, by W. H. Thompson (1868); *Apol.*, by W. Wagner (Camb., 1869), and James

Riddell (Oxford, 1877); *Gorg.*, by W. H. Thompson (1871); and *Parm.*, by Maguire (Dublin, 1882). *French*.—Hirschig and Schneider (in Didot's *Bibliotheca Scriptæ Græc.*, Paris, [1836] 1873). *Separate Dialogues*.—*Apologie de Socrate*, by H. David (Paris, 1866); *Phædo*, by Bellin (Paris, 1878). *Italian*.—*Protag.*, by G. Oliva (Florence, 1877).

TRANSLATIONS.—*Latin*.—*Marsili Ficini cum vita Platonis* (Venice, 1517; this is the basis of Latin translations accompanying later editions, such as that of Bekker, 1816-23, said to have been revised by F. A. Wolf, and that of Hirschig and Schneider; Didot, Paris, [1853] 1873). *Single Dialogues*.—*Timæus* (Chalcidius, 1579, and Cambridge, 1670); *Gorgias* and *Apologia*, by Leonardo Aretino. *German*.—J. F. Kleuker (6 vols., Lemgo, [1778] 1797); Schleiermacher (with Introductions, Berlin, [1804] 1810); Engelmann (with text and commentary, [1841] 1877); J. F. Drescher, *Apol.*, *Crit.*, *Phæd.*, *Symp.*, *Gorg.*, *Protag.* (Gießen, [1848] 1854); Hieron. Müller (with introd. by Steinhardt, [1850] 1874); Georg. Susemihl, *Jul. Deutsche*, W. S. Teuffel, and W. Wegmann (Stuttgart, [1853] 1876); Prantl and others (Stuttgart, [1854] 1875). *English*.—Floyer Sydenham ([1759] 1776); Thomas Taylor (the complete edition, including the nine dialogues translated by Sydenham, Lond., 1804); W. Whewell (*Plot. Dial. for Eng. Readers*, Camb., 1860, contains portions of original translation); B. Jowett (with Introductions, 4 vols., 1871; 5 vols., Oxford, 1875; see also *Critical Works*); selections from Jowett by C. A. H. Bulkey (*The Wisdom of Plato*, New York, 1876). *Separate Dialogues*.—*Republic*, by Spens (Glasgow, 1763); by Davies and Vaughan ([1852] 1866), and by Jowett (publ. separately, 1881); *Symposium*, *Jon. Menæxenus*, by Shelley ([1822] 1840); *Philebus*, by Poste (1860) and F. A. Paley (1873); *Gorgias*, by Cope (1864); *Sophistes*, and *Menos* to 69, by Mackay (1858); *Theætetus*, by F. A. Paley (1875); *Phædo*, by Cope (1875); "Euthyphro," "Apology," "Crito," and "Phædo," by F. J. Church (*The Trial and Death of Socrates*, London, 1880). *French*.—André Dacler, *Les Œuvres de Platon en Français* (2 vols., Paris, 1699), and *Works abridged with notes*, by M. Dacler (2 vols., 3d ed., London, 1878); Victor Cousin, *Œuvres traduites avec arguments et notes* (13 vols., [1822] 1840); Thurot, *Œuvres de Platon*, *Traductions sous la direction de Émile Saisset* (1878), transl. of *Crito* (see above). *Italian*.—Dardi Bembo, *Delle opere di Platone tradotte in lingua volgare* (Venice, 1601); Ruggiero Bonghi (vols. I, II, Milan, 1858); E. Ferrai (Padua, 1873-74). *Separate Dialogues*.—*Euthyphr.*, *Apol.*, *Crit.*, *Phæd.*, *Tim.*, by Seb. Erizzo (Venice, 1579). *Swedish*.—Translation begun (Stockholm, 1870-72).

LEXICONS.—*Timæus*, ed. Ruhnken (Leips., [1754] 1833); Wagner, *Wörterbuch der Platonischen Philosophie* (Göttingen, 1799); Ast, *Lexicon Platonicum* (Leips., [1855] 1838).

SPECIAL STUDIES ON THE LANGUAGE OF PLATO.—Braun, *De Hyperbato Platonico* (Culm., [1846-47] 1847-52); Engelhardt, *De periodorum Platoniorum Structura* ([1853] 1864); M. Schanz, "Bifurcation der hypothetischen periodo nach Platon" (in *Floekelsen's Neues Jahrbücher*, Leipzig, 1870); and Riddell, "Digest of the Platonic Idioms," in his edition of the *Apology*.

ON THE MSS.—Cornarius, *Eclogæ* (ed. Fischer, Leips., 1771); F. J. Bast, *Kritischer Versuch über den Text des Platon* (Leips., 1794); Gaisford, *Lectiones Platonice* (Oxford, 1820); Bekker, *Commentaria* to his ed. (1823); M. Schanz, *Novæ Commentationes Platonice* (Würzburg, 1871); *Studien zur Geschichte des Platonischen Textes* (Würzburg, 1874); and *Ueber den Platonischen Codex des Marcus Bibliothek in Venedig* (Leips., 1877), &c.

LITERARY OR PHILOSOPHICAL CRITICISM ON PLATO.—*German and Dutch*.—Morgenstern, *Commentaria de Republica* (1794); Schleiermacher, *Introductions to his translation* ([1801] 1810; see also Dobson); Böckh, *Kleine Schriften* (vols. III, IV, from 1806); J. A. Grimm, *De Epistolis Platonis* (comp. Karsten, 1864) 1815; F. Ast, *Plato's Leben und Schriften* (1818); Trendelenburg, *De Numeris* (1826); Van Heusde, *Intitla Philosophiæ Platonice* (Utrecht, [1827] 1831; 2d ed., Leyden, 1842); K. F. Hermann, *Geschichte u. System der Plat. Philosophie* (Heldelberg, 1838), and *Disputatio de republicæ Platonice temporibus* (Marburg, 1839); Zeller, *Philosophie der Griechen* (vol. II., [1839] 1859); Steinhardt, *Introductions*, to Hieron. Müller's translation (1850); Suckow, *Die Wissenschaftliche u. künstlerische Form der Platonischen Schriften* (Berlin, 1855); Susemihl, *Die genetische Entwicklung der Plat. Philosophie* (Leips., [1855] 1860); E. Alberti, *Zur Dialektik des Platon* (1856); E. Munk, *Die natürliche Ordnung der Plat. Schriften* (Berlin, 1857); Döllinger, in *Heidenthum u. Bønn, in his *Greek Philosophers* (1882). *French*.—Paul Janet, *Études sur la Dialectique* (Paris, 1860); Martin, *Études sur la Timée* (Paris, 1841).

PLATON, LEVSHIN (1737-1812), a celebrated Russian archbishop, was born at the village of Tchashnikovo, near Moscow, in 1737, and was educated in the academy of that city. On completing his studies there in 1758 he was appointed teacher of rhetoric in the school connected with the monastery of St Sergius, and about this time entered the priesthood. In 1763 Catherine invited him to instruct her son Paul in theology, and he became one of the court chaplains. Three years afterwards Platon was appointed archimandrite of the monastery of the Trinity (Troitzkain Lavra) near Moscow; in 1770 he was made archbishop of Tver, and finally in 1787 archbishop of Moscow and metropolitan. He died in 1812. Platon was a brilliant and learned man, not only in the opinion of his countrymen, but in the estimation of all foreigners who made his acquaintance. We get a graphic and interesting picture

of him at the beginning of the present century in the travels of Edward Clarke of Cambridge, who was much struck with his wit and wide range of reading. As a preacher he enjoyed great celebrity, one of the most remarkable specimens of his eloquence being the sermon preached at the coronation of Alexander I. He was also the author of several works which enjoyed considerable reputation in their time, such as *A Short Course of Divinity*, compiled for the use of the emperor Paul when grand-duke, several *Catechisms*, *A Short History of the Russian Church*, which has been translated into English, and other works. Platon is altogether a striking and important figure in a very eventful period of his country's history.

PLATTNER, CARL FRIEDRICH (1800-1858), a famous scientific metallurgist, was born in Kleinwaltersdorf, near Freiberg in Saxony, on the 2d January 1800, and died

in the latter town on the 22d January 1858. Plattner's father, though only a poor working miner, found the means for having his son educated first at the "Bergschule" and then at the "Bergakademie" of Freiberg. After having completed his curriculum there in 1820, he obtained a position in connexion with the royal mines and metal works, and was employed chiefly as an assayer, in which capacity he soon became conspicuous by his rare exactness and circumspection, and his constant striving after scientific advancement.

The mouth-blowpipe, after doing service for centuries to metal-workers as a soldering tool (hence the German name *Löthrohr*), in the hands of Gahn and subsequently of Berzelius became the most useful of instruments for the qualitative testing of mineral substances. Through the efforts of the latter, in fact, blowpipe analysis had developed into almost an independent branch of analysis. But nobody dreamt of quantitative mouth-blowpipe assaying until Harkort in 1827 (while a student in the Freiberg academy) succeeded in working out a blowpipe-assay for silver. Harkort stopped there; but the idea of blowpipe-assaying was taken up subsequently by Plattner, who, by bringing his characteristic thoroughness, indefatigability, and unexampled dexterity to bear on the subject, succeeded in working out reliable methods for all the ordinary useful metals. His modes of assaying for cobalt and nickel more especially quickly found favour with metallurgists, because they were more exact than the then known corresponding methods of "wet-way" analysis, and required a less number of hours than the latter required of days for their execution. Our analytical methods for the determination of cobalt have since become far more perfect but no less troublesome, and to the present day Plattner's nickel-assay is the most precise method for the estimation of this metal in complex mixtures.

Plattner, while working at this specialty of his own, at the same time overhauled the entire field of qualitative blowpipe assaying, and ultimately summed up the whole of his vast experience in his *Probirkunst mit dem Löthrohr*, which soon became, and to the present day ranks as, the standard book on the subject. Since its first publication in 1835 the work has gone through four editions, apart from two independent English translations.

With all his high and recognized distinction in his own specialty, Plattner most keenly felt that his scientific education in Freiberg had been somewhat one-sided; and in 1839 he left his post and family to work for a year in Heinrich Rose's laboratory in Berlin, and supplement his knowledge of modern methods of chemical analysis. While there as a student he at the same time acted as a teacher in his branch, and won the lasting friendship of a number of distinguished scientific men. On his return home in 1840 he was raised to the rank of assessor at the Government board of mining and metallurgy, and made chief of the royal department of assaying. In 1842 he was deputed to complete a course of lectures on metallurgy in the Bergakademie which had been commenced by Lampadius; and he subsequently became Lampadius's successor as professor of that branch, and for the then newly instituted course of blowpipe-assaying. In addition to these functions he instituted, in 1851, a special course on the metallurgy of iron. He continued lecturing in the academy as long as he was able,—until the session of 1856–57. It was during this period of professorial activity that he made the extensive studies and experimental researches which form the basis of his work *Die metallurgischen Röstprocesse theoretisch betrachtet* (Freiberg, 1856). His well-known *Vorlesungen über allgemeine Hüttenkunde* (vol. i. and ii., Freiberg, 1860) is a posthumous publication edited by Prof. Thomas Richter.

In addition to these great works (and the *Probirkunst*) Plattner published (in *Erdmann's Journal* and in *Schweigger's Journal* and elsewhere) numerous memoirs on metallurgical or mineralogical subjects, regarding which we must confine ourselves to saying that they mark him as an investigator of rare diligence and power. How he found time for all his original work is difficult to say; it certainly did not cause him to neglect his students. He attended to them in the most conscientious and efficient manner, as hundreds of his pupils all over the world can testify. His marked success as a teacher was no doubt owing greatly to his high personal qualities,—his cheerful, untiring, unselfish devotion to duty, his kindness of heart and manner, his freedom from all cant and morbid ambition. The latter years of his life were embittered by intense suffering. After a long period of lingering illness he succumbed to a disease of the brain.

PLATTSBURGH, a village and township of the United States, the shire-town of Clinton county, New York, and the port of entry of Champlain customs district, lies on the west side of Lake Champlain at the mouth of the Saranac. By rail it is 168 miles north of Albany and 73 south-south-east of Montreal (Canada). A branch line runs 20 miles south-west to Au Sable and forms a favourite route to the Adirondacks, and the Chateaugay Railroad runs 34 miles west by north to Lyon Mountain, where there are extensive iron mines. Plattsburgh contains county buildings and court-house, a custom-house, a high school, and a small public library. It has nail and waggon factories, flour-mills, saw-mills, an iron furnace, machine shops, and a large sewing-machine manufactory. It is a garrison town of the United States army, with extensive barracks about a mile south of the village. The value of the imports and exports of the district for the year ending June 30th 1884 was \$3,169,780 and \$1,319,422; and 1279 vessels entered from Canada, while 1179 cleared. The aggregate burthen of the vessels belonging to the district was 57,477 tons. In 1870 the township had 8414 inhabitants, the village 5139; in 1880 the figures were 8283 and 5245.

Plattsburgh dates from 1785. It has twice been destroyed by fire (1849 and 1867). In 1812 it became the headquarters of the U.S. army on the northern frontier; and in September 1814 it was rendered famous through the capture of the British flotilla under Commodore Downie by the United States flotilla under Commodore Macdonough, and the consequent retreat across the Saranac of Sir George Prevost, who had been attacking the village with a powerful army. Downie and fifteen other officers of the contending forces are buried in Plattsburgh cemetery.

PLATYPUS. The Duck-billed Platypus (*Platypus anatinus*) was the name assigned to one of the most remarkable of known animals by Shaw, who had the good fortune to introduce it to the notice of the scientific world in the *Naturalist's Miscellany* (vol. x., 1799). In the following year it was independently described by Blumenbach (*Voigts Magazin*, ii. p. 205) under the name of *Ornithorhynchus paradoxus*. Shaw's generic name, although having priority to that of Blumenbach, could not be retained, as it had been used at a still earlier time (1793) by Herbst for a genus of *Coleoptera*. *Ornithorhynchus* is therefore now universally adopted as the scientific designation, although Duck-billed Platypus may be conveniently retained as a vernacular appellation. By the colonists it is called "Water-Mole," but its affinities with the true moles are of the slightest and most superficial description.

The anatomical differences by which the platypus, and its only ally the echidna, are separated from all other mammals, so as to form a distinct subclass with relationship to the inferior vertebrated classes, have been described in the article MAMMALIA (vol. xv. pp. 371 and 377), where

also will be found the main distinctive characters of the two existing representatives of the group. It is there stated that the early stages of the development of the young are not yet fully known; in fact this was till very recently one of the most interesting problems in zoology to be solved. It has been repeatedly affirmed, in some cases by persons who have had actual opportunities of observation, that the platypus lays eggs; but these statements have been generally received with scepticism and even denial. This much-vexed question has, however, been settled by the researches of Mr W. H. Caldwell (1884), who has found that these animals, although undoubtedly mammals throughout the greater part of their structure, are oviparous, laying eggs, which in the manner of their development bear a close resemblance to the development of those of the *Reptilia*. Two eggs are produced at a time, each measuring about three-fourths of an inch in its long and half an inch in its short axis, and enclosed in a strong, flexible, white shell.

The platypus is pretty generally distributed in situations suitable to its aquatic habits throughout the island of Tasmania and the southern and eastern portions of Australia. Slight variations in the colouring and size of different individuals have given rise to the idea that more

Platypus. From Gould's *Mammals of Australia*.

than one species may exist; but all naturalists who have had the opportunity of investigating this question by the aid of a good series of specimens have come to the conclusion that there is but one; and no traces of any extinct allied forms have yet been discovered.

The length of the animal when full grown is from 18 to 20 inches from the extremity of the beak to the end of the tail, the male being slightly larger than the female. The fur is short, dense, and rather soft to the touch, and composed of an extremely fine and close under-fur, and of longer hairs which project beyond this, each of which is very slender at the base, and expanded, flattened, and glossy towards the free end. The general colour is deep brown, but paler on the under parts. The tail is short, broad, and depressed, and covered with coarse hairs, which in old animals generally become worn off from the under surface. The eyes are small and brown. There is no projecting pinna or ear-conch. The mouth, as is well known, bears a striking resemblance to the bill of a duck. It is covered with a naked skin, a strong fold of which projects outwards around its base. The nostrils are situated near the extremity of the upper surface. There are no true teeth, but their purposes are served by horny prominences,

two on each side of each jaw,—those in the front narrow, longitudinal, sharp-edged ridges, and those behind broad, flattened, and molariform. The upper surface of the lateral edges of the mandible has also a number of parallel fine transverse ridges, like those on the bill of a duck. In the cheeks are tolerably capacious pouches, which appear to be used as receptacles for food.

The limbs are strong and very short, each with five well-developed toes provided with strong claws. In the fore feet the web not only fills the interspaces between the toes, but extends considerably beyond the ends of the long, broad, and somewhat flattened nails, giving great expanse to the foot when used for swimming, though capable of being folded back on the palm when the animal is burrowing or walking on the land. On the hind foot the nails are long, curved, and pointed, and the web extends only to their base. On the heel of the male is a strong, curved, sharply pointed, movable horny spur, directed upwards and backwards, attached by its expanded base to the accessory bone of the tarsus. This spur, which attains the length of nearly an inch, is traversed by a minute canal, terminating in a fine longitudinal slit near the point, and connected at its base with the duct of a large gland situated at the back part of the thigh. The whole apparatus is so exactly analogous in structure to the poison gland and tooth of a venomous snake as to suggest a similar function, but evidence that the platypus ever employs its spur as an offensive weapon has, at all events until lately, been wanting. A case is, however, related by Mr Spicer in the *Proceedings* of the Royal Society of Tasmania for 1876 (p. 162) of a captured platypus inflicting a severe wound by a powerful lateral and inward movement of the hind legs, which wound was followed by symptoms of active local poisoning. It is not improbable that both the inclination to use the weapon and the activity of the secretion of the gland may be limited to the breeding season, and that their purpose may be, like that of the antlers of deer and many similar organs, for combat among the males. In the young of both sexes the spur is present in a rudimentary condition, but it disappears in the adult females.

The platypus is aquatic in its habits, passing most of its time in the water or close to the margin of lakes and streams, swimming and diving with the greatest ease, and forming for the purpose of sleeping and breeding deep burrows in the banks, which generally have two orifices, one just above the water level, concealed among long grasses and leaves, and the other below the surface. The passage at first runs obliquely upwards in the bank, sometimes to a distance of as much as 50 feet, and expands at its termination into a cavity, the floor of which is lined with dried grass and leaves, and in which the eggs are laid and the young brought up. Their food consists of aquatic insects, small crustaceans, and worms, which are caught under water, the sand and small stones at the bottom being turned over with their bills to find them. They appear at first to deposit what they have thus collected in their cheek pouches, and when these are filled they rise to the surface and quietly triturate their meal with the horny teeth before swallowing it. Swimming is effected chiefly by the action of the broad forepaws, the hind feet and tail taking little share in locomotion in the water. When asleep they roll themselves into a ball, as shown in the figure. In their native haunts they are extremely timid and wary, and very difficult to approach, being rarely seen out of their burrows in the daytime. Mr A. B. Crowther, who has supplemented the often quoted observations of Dr George Bennett upon the habits of these animals in confinement, says, "They soon become very tame in captivity; in a few days the young

ones appeared to recognize a call, swimming rapidly to the hand paddling the water; and it is curious to see their attempts to procure a worm enclosed in the hand, which they greedily take when offered to them. I have noticed that they appear to be able to smell whether or not a worm is contained in the closed hand to which they swim, for they desisted from their efforts if an empty fist was offered." When irritated they utter a soft low growl, resembling that of a puppy. (W. H. F.)

PLAUEN, a busy manufacturing town of Saxony, in the government district of Zwickau, is situated on the Elster, 60 miles to the south of Leipsic. It was formerly the capital of the Voigtland, a territory governed directly by the imperial voigts or bailiffs, and this name still clings in popular speech to the hilly manufacturing district in which it lies. The most prominent buildings are the fine Gothic church of St John, the town-house (about 1550), the new post-office, and the loftily-situated old castle of Hradschin, now occupied by a law court. Plauen is now the chief place in Germany for the manufacture of embroidered white goods of all kinds, and for the finishing of woven cotton fabrics. Dyeing, tanning, bleaching, and the making of paper and machinery are also prosecuted; and an active trade is carried on in these various industrial products. In 1880 the town contained 35,078 inhabitants and in 1884 above 40,000, almost all Protestants.

As indicated by the name of the castle, Plauen was probably founded by the Slavs, after whose expulsion it was governed directly by the imperial bailiffs. In 1327 it became a Bohemian fief, but passed into the possession of Saxony in 1466 and remained permanently united to it from 1569 onwards. The manufacture of white goods was introduced by Swabian or Swiss immigrants about 1570, and since then the prosperity of the town has been great, in spite of the storms of the Thirty Years' and Seven Years' Wars. The advance of Plauen has been especially rapid since its incorporation in the Zollverein.

PLAUTUS, T. Maccius, was the greatest comic and dramatic genius of Rome, and still ranks among the great comic dramatists of the world. While the other creators of Roman literature, Nævius, Ennius, Lucilius, &c., are known to us only in fragments, we still possess twenty plays of Plautus. A few of them are incomplete, and in some cases they show traces of later interpolations, but they have reached us in the main as they were written by him in the end of the 3d and the beginning of the 2d century B.C. At the date of his birth Roman literature may be said to have been non-existent. When he died the Latin language had developed its full capacities as an organ of social intercourse and familiar speech, and the literature of the world had been enriched by a large number of adaptations from the New Comedy of Athens, animated by the new life of ancient Italy and vivified by the genius and robust human nature of their author; and these have been the chief means of transmitting the traditions of the ancient drama to modern times. The maturity which comedy attained in a single generation affords a remarkable contrast to the slow processes by which the higher forms of Roman poetical and prose literature were brought to perfection. It may be explained partly by the existence, for some generations before the formal beginning of literature at Rome, of the dramatic and musical medleys ("saturne impletæ modis") which in their allusions to current events and their spirit of banter must have had a considerable affinity with the dialogue of Plautus, and partly to the diffusion of the Latin language, as the organ of practical business among the urban communities of Italy. But much also was due to the individual genius and the command over their native idiom possessed by the two oldest of the genuine creators of Roman literature, Nævius and Plautus.

A question might be raised as to whether Plautus or

his younger contemporary Ennius was the most characteristic representative of the national literature of their time. Ennius certainly exercised a much more important influence on its subsequent development. He arrested the tendency imparted to that development by Nævius and Plautus. He made literature the organ of the serious spirit and imperial ambition of the Roman aristocracy, while the genius of Plautus appealed to the taste and temperament of the mass of the people, at a time when they were animated by the spirit of enjoyment and comparatively indifferent to political questions. The ascendancy of the aristocracy in public affairs for two generations after the end of the Second Punic War determined the ascendancy of Ennius in Roman literature; and it may be admitted that, if the genius of Plautus and of Ennius could not work harmoniously together, it was best that that of the younger poet, as representative of the truer genius of Rome, should prevail. The popularity of Plautus was greatest in his own time and in the generation succeeding him, but his plays still continued to be acted with applause till the age of Cicero, and he was greatly admired both by Cicero and by the man among his contemporaries who, both from his learning and taste, retained most of the antique spirit, Varro. The literary taste of the Augustan age and of the first century of the empire was adverse to him; but the archaic revival in the latter part of the 2d century of our era brought him again into favour, with the result of securing the preservation of his works through mediæval times and their revival with great acceptance at the Renaissance. That his original popularity was due to genuine gifts of humour and genuine power in representing human life is clear from their reception by a world so much altered from that in which he himself had played his part. And if his influence was not felt like that of Ennius in determining the form and spirit of the literature of his country, it was not without effect on the two greatest dramatists of modern times, Shakespeare and Molière.

The few facts known of his life rest on the authority of Cicero, of Aulus Gellius, and of Jerome in his continuation of the Eusebian *Chronicle*. He was born in the earlier half of the 3d century B.C., and died at an advanced age in the year 184 B.C. He was a native of Sarsina in Umbria. His first employment was in some way connected with the stage "in operis artificum scenicorum." He saved money in this employment, engaged in foreign trade, and returning to Rome in absolute poverty was reduced to work as a hired servant in a mill; and then for the first time he began to write comedies. The earliest allusion to any contemporary event which we find in any of his plays is that in the *Miles Gloriosus* (l. 212-3) to the imprisonment of Nævius, which happened about the year 207 B.C. The *Cistellaria* and *Stichus* were apparently written immediately after the end of the Second Punic War. The last ten years of his life were the most productive, and the greater number of his extant comedies belong to that period. They do not seem to have been published as literary works during his lifetime, but to have been left in possession of the players, to whom the interpolations and some other unimportant changes are to be ascribed. The prologues to the plays, with three or four exceptions, belong to the generation after his death. In a later age the plays of many contemporary playwrights were attributed to him. Twenty-one were accepted by Varro as undoubtedly genuine, and of these we possess twenty nearly complete, and fragments of another, the *Vidularia*. Other nineteen Varro regarded as probably genuine, and the titles of some of them, e.g., *Saturio*, *Addictus*, *Commorientes*, are also known to us.

We get the impression from his works and from ancient

criticisms on them that he was, in his latter years, a rapid and productive writer, more concerned with the immediate success of his works than with their literary perfection.<sup>1</sup> Yet he shows that he took pride and pleasure in his art (*Bacch.*, 214), and Cicero testifies especially to the gratification which he derived from two works of his old age, the *Pseudolus* and *Truculentus* (*De Senec.*, 14). We get further the impression of a man of strong animal spirits and of large intercourse with the world, especially with the trading and middle classes. We find no indication of familiarity with the manners, tastes, or ideas of the governing aristocracy. The story told of his unsuccessful mercantile speculations might seem to derive confirmation from the "flavour of the sea" and the spirit of adventure present in many of his plays, from his frequent colloquial use of Greek phrases, and from indications of familiarity with the sights, manners, and pleasures of the Greek cities on the Mediterranean. He has many allusions to works of art, to the stories of Greek mythology, and to the subjects of Greek tragedies; and he tried to enrich the native vocabulary with a considerable number of Greek words which did not maintain their place in the language. The knowledge of these subjects which he betrays, and his copious use of Greek words and phrases, seem to be the result rather of active and varied intercourse with contemporary Greeks than of the study of books.

Like all the old Roman dramatists, he borrows his plots, incidents, scenes, characters, and probably the outlines of his dialogue from the authors of the new comedy of Athens,—Diphilus, Philemon, Menander, and others. But he treated his borrowed materials with much more freedom and originality than the only other dramatist of whom we possess complete pieces—Terence. A note of this difference appears in the fact that the titles of all the plays of Terence are Greek, while those of Plautus are nearly all Latin. We find a much greater range and variety in the scenes and incidents introduced by Plautus, and much greater divergence from a conventional type in his characters. But it is especially on his dialogue and his metrical soliloquies that his originality is stamped. Though all the personages of his plays are supposed to be Greeks, living in Greek towns, they constantly speak as if they were Romans living in the heart of Rome. Frequent mention is made of towns in Italy, of streets, gates, and markets in Rome itself, of Roman magistrates and of their duties, of the business of the law-courts, the comitia, and the senate, &c. We constantly meet with Roman formulae, expressions of courtesy, proverbs, and the like. While avoiding all direct reference to politics, he frequently alludes to recent events in Roman history, and to laws of recent enactment. Although he maintains and seems to inculcate an attitude of political indifference, he is not altogether indifferent to social conditions, and in more than one of his plays comments on the growing estrangement between the rich and poor, as an element of danger to the state. Still he writes neither as a political nor as a social satirist, but simply with the wish to represent the humours of human life and to amuse the people in their holiday mood.

His independence of his originals, in regard to expression, is further shown by the puns and plays on words, the alliterations, assonances, &c., which do not admit of being reproduced in translation from one language to another; in the metaphors taken from Roman military operations, business transactions, and the trade of various artisans; and in his profuse use of terms of endearment and vituperation, characteristic of the vivacity of the Italian temperament in modern as in ancient times. But in nothing is his difference from Terence, and presum-

ably from the originals which they both followed, more decided than in his large use of lyrical monologue, or "cantica," alternating with the ordinary dialogue in much the same way as the choral odes do in the old Greek comedy. These one may conjecture to have been a partial survival of passages in the old dramatic *satyræ*, which were repeated to a musical accompaniment. In the naiveté of the reflexions which they contain, and the prolixity with which the thought is worked out, we recognize the earliest effort of the Roman mind applied to reflexion on life, and no reproduction of any phase of the Greek mind to which the expression of such reflexion had been familiar for generations.

In the diction of Plautus accordingly we may consider that we have a thorough reflexion of his own mind, and an important witness of Roman life and thought in his time. The characters in his plays are the stock characters of the New Comedy of Athens, the "fallax servus," the "leno insidiosus," the "meretrix blanda," the "parasitus edax," the "amans ephebus," the "pater attentus," &c. We may miss the finer insight into human nature and the delicate touch in drawing character which Terence presents to us in his copies from Menander, but there is wonderful life and vigour, and considerable variety in the embodiment of these different types by Plautus. The characters of Ballio and Pseudolus, of Euclio in the *Aulularia*, of the two Menæchmi, and of many others have a real individuality, which shows that in reproducing Greek originals Plautus thoroughly realized them and animated them with the strong human nature of which he himself possessed so large a share. For his plots and incidents he has been much more indebted to his originals. There is a considerable sameness in many of them. A large number turn upon what are called "frustrationes"—tricks by which the slave who plays the principal part in the comedy succeeds in extracting either from the father of his young master or from some other victim a sum of money to aid his master in his love affairs. But Plautus, if not more original, is more varied than Terence in his choice of plots. In some of them the passion of love plays either no part or a subordinate one. He also varies his scenes much more than Terence. Thus in some of his plays we find ourselves at Epidamnus, at Ephesus, at Cyrene, and not always in Athens.

The following is a list of the comedies according to their usual arrangement, which is nearly, but not strictly alphabetical:—*Amphitruo*, *Asinaria*, *Aulularia*, *Captivi*, *Curculio*, *Casina*, *Cistellaria*, *Epidicus*, *Bacchides*, *Mostellaria*, *Menæchmi*, *Miles Gloriosus*, *Mercator*, *Pseudolus*, *Penulus*, *Persa*, *Rudens*, *Stichus*, *Trinummus*, *Truculentus*. Of these the most generally read, and on the whole the most interesting, are the *Aulularia*, *Captivi*, *Menæchmi*, *Miles Gloriosus*, *Mostellaria*, *Pseudolus*, *Rudens*, and *Trinummus*. Besides these the *Amphitruo*, *Bacchides*, and *Stichus* (although the last two are incomplete) are of special interest. The *Amphitruo* is altogether exceptional, and gives, perhaps, as high an idea both of the comic and of the imaginative power of the author as any of the others. The interest attaching to it is enhanced by the fact that it has been imitated both by Molière and Dryden, that attaching to the *Aulularia* by its having suggested the subject of *L'Avare* of the French dramatist, and to the *Menæchmi* by the reappearance of its principal motive in the *Comedy of Errors* of Shakespeare. The *Captivi* was characterized by Lessing as the best constructed drama in existence. It may be classed with the *Rudens* as appealing to a higher and purer class of feelings, and as coming nearer to the province of serious poetry, than any other extant specimens of Latin comedy. The *Aulularia* and *Trinummus* may be mentioned along with these as bringing us into contact with characters more estimable and attractive than these in the great majority of the other pieces.

While there are abundant good sense and good humour in the comedies of Plautus, and occasional touches of pathos and elevated feeling in one or two of them, there is no trace of any serious purpose behind his humorous scenes and representations of character. He presents a remarkable exception to the didactic and moralizing spirit which appears in most of the leading representatives of Roman literature. He is to be judged on the claim

<sup>1</sup> "Scurus cadit an recto stet fabula talo."—Hor. *Ep.* ii. 1, 176.

which is put forward in the epitaph which in ancient times was attributed to himself:—

"Postquam est mortem aptus Plautus, comedia inquit,  
Scena est deserta, delinquit, ludu' focusque,  
Et numeri innumeri simul omnis conlacrumant."<sup>1</sup>

He has not the more subtle and penetrating irony which we recognize in Terence, in Horace, and in Petronius; still less can we attribute to him the "rigidi censura carchinni" which accompanied and inspired the humorous fancies of Lucilius and Juvenal. But among all the ancient humorists, with the exception of Aristophanes, he must have had the power of immediately provoking the heartiest and broadest mirth and laughter. He was too careless in the construction of his plots to be a finished dramatic artist. He was apparently more popular among the mass of his countrymen than any Roman author of any age; but to be thoroughly popular he had to satisfy the tastes of an audience accustomed to the indigenous farces of Italy. This is the defect, according to the judgment of educated critics in the Augustan age, which Horace indicates in the line

"Quantus est Docennus edacibus in paratis."

But he had the most wonderful power of dramatic expression of feeling, fancy, and character by means of action, rhythm, and language. In the line in which Horace expresses the more favourable criticism of his time,—

"Plautus ad exemplar Stulti properare Epicharmi,"—

the term *properare* expresses the vivacity of gesture, dialogue, declamation, and recitative in which the plays of Plautus never fail, and which must have made them admirable vehicles for the art of the actor. The lyrical recitative occupies a much larger place in his comedies than in those of Terence, and in them he shows the true poetical gift of adapting and varying his metres in accordance with the moods and fancies of his characters. But the gift for which he is pre-eminent above almost every other Roman author is the vigour and exuberant flow of his language. No other writer enables us to feel the life and force of the Latin idiom, undisturbed by the mannerisms of a literary style, in the same degree. Among the masters of expression in which the prose and poetical literature of Rome abounds, none was more prodigally gifted than Plautus, and this gift of expression was the accompaniment of the exuberant creativeness of his fancy and of the strong vitality and lively social nature which was the endowment of the race to which he belonged.

In the beginning of the 15th century only the first eight plays (from *Amphitruo* to *Epidicus*) were in circulation. The other twelve were recovered in the course of that century, and two new manuscripts, one of them containing the whole twenty, were discovered in the following century. The Ambrosian palimpsest, discovered in 1515, has been recognized as the most trustworthy text for those plays which it preserves, and it is on this that the critical labours of Ritschl have been based. His great critical edition is being continued by his pupils G. Loewe, G. Gutz, Fr. Schell. An edition of the plays with a commentary by Professor Usinger of Copenhagen is now nearly complete. The most useful editions of separate plays are those of Lorenz and Brix. (W. Y. S.)

PLAYFAIR, JOHN (1718–1819), mathematician and physicist, was born at Benzie, Forfarshire, where his father was parish minister, on March 10, 1718. He was educated at home until the age of fourteen, when he entered the university of St Andrews. Ability for scientific studies must have appeared very early with him, for while yet a student he was selected to teach natural philosophy during the occasional absence of the professor. In 1766, when only eighteen, he was candidate for the chair of mathematics in Marischal College, Aberdeen, and, although he was unsuccessful, his claims were admitted to be high. Six years later he made application for the chair of natural philosophy in his own university, but again without success, and in 1773 he was offered and accepted the living of the united parishes of Liff and Benzie, vacant by the death of his father. He continued, however, to carry on his mathematical and physical studies, and in 1782 he resigned his charge in order to become the tutor of Ferguson of Raith. By this arrangement he was able to be frequently in Edinburgh, and to cultivate the literary and scientific society for which it was at that time specially distinguished; and through Maskelyne, whose acquaintance he had first made in the course of the celebrated Schiehallion experiments in 1774, he also gained access to the scientific circles of London. In 1785 when Dugald Stewart succeeded Ferguson in the Edinburgh chair

of moral philosophy, Playfair succeeded the former in that of mathematics. In 1802 he published a volume entitled *Illustrations of the Huttonian Theory of the Earth*, and in 1805 he exchanged the chair of mathematics for that of natural philosophy in succession to Robison, whom also he succeeded as general secretary to the Royal Society of Edinburgh. He took a prominent part, on the liberal side, in the ecclesiastical controversy which arose in connexion with Leslie's appointment to the post he had vacated, and published a satirical *Letter* (1806) which was greatly admired by his friends. His election as a fellow of the Royal Society took place in 1807. In 1815, after the establishment of a European peace, he made a journey through France and Switzerland to Italy, and remained abroad for nearly eighteen months, interesting himself chiefly in the geology and mineralogy of the districts he visited. After a few years of gradually failing health he died on July 19, 1819.

A collected edition of Playfair's works, with a memoir by James G. Playfair, appeared at Edinburgh in 4 vols. 8vo. His writings include a number of essays contributed to the *Edinburgh Review* from 1804 onwards, various papers in the *Phil. Trans.* (including his earliest publication "On the Arithmetic of Impossible Quantities," 1779, and an "Account of the Lithological Survey of Schiehallion" 1811) and in the *Transactions* of the Royal Society of Edinburgh ("On the Causes which affect the Accuracy of Barometrical Measurement," &c.), also the articles "Epinus" and "Physical Astronomy," and a "Dissertation on the Progress of Mathematical and Physical Science since the Revival of Learning in Europe," in the *Encyclopædia Britannica* (Supplement to fourth, fifth, and sixth editions). His *Elements of Geometry* first appeared in 1795 and have passed through many editions; his *Outlines of Natural Philosophy* (2 vols., 1812–16) consist of the propositions and formulae which were the basis of his class lectures. Playfair's contributions to pure mathematics were not considerable, his paper "On the Arithmetic of Impossible Quantities," that "On the Causes which affect the Accuracy of Barometrical Measurements," and his *Elements of Geometry*, all already referred to, being the most important. As a mathematician simply he was far inferior to the first two Gregorys, to Colin Maclaurin, and even to Matthew Stewart. He was, however, a man of great general ability and was conspicuous for a calm intellect. His scientific style was a model of clearness, and his *Illustrations of the Huttonian Theory of the Earth* attained great popularity through its literary merits. His lives of Matthew Stewart, Hutton, Robison, many of his reviews, and above all his "Dissertation" are of the utmost value. The English mathematicians of his day professed unlimited admiration of Newton, but few of them were found able to wield his weapons, and the majority had come simply to rest under the shadow of that great man; to Playfair belongs the credit of having been one of the first to diffuse among his countrymen a knowledge of the substantial progress which the infinitesimal calculus had been making in the hands of the Continental analysts.

PLEADING, in law, denotes in civil procedure the statement in legal form of the grounds on which a party to an action claims the decision of the court in his favour, in criminal procedure the accusation of the prosecutor or the answer of the accused. The term "pleadings" is used for the collected whole of the statements of both parties, the term "pleading" for each separate part of the pleadings. A pleading may be the statement of either party; a "plea" is (except in Scots and ecclesiastical law) confined to the defence made by an accused person. To "plead" is to frame a pleading or plea.

All systems of law agree in making it necessary to bring the grounds of a claim or defence before the court in a more or less technical form. In Roman law the action passed through three stages (see *ACTIO*), and the manner of pleading changed with the action. In the earliest historical period, that of the *legis actiones*, the pleadings were verbal, and made in court by the parties themselves, the proceedings imitating as far as possible the natural conduct of persons who had been disputing, but who suffered their quarrel to be appeased (Maine, *Ancient Law*, ch. x.). Though pleadings were probably not couched in technical language originally, this soon became a necessity,

<sup>1</sup> "After Plautus died, comedy mourns, the stage is deserted, then laughter, mirth, and jest, and his numberless numbers all wept in concert."

and was regarded as so important that, as Gaius tells us, the party who made even the most trifling mistake would lose his suit. This excessive reverence for formality is a universal characteristic of archaic law. Its probable explanation is to be found in the weakness of the executive. In the second period, that of the procedure by *formula*, the issue which the *iudex* decided was made up by the *prætor* in writing from the statements of the parties before him. The *formula* was a short summary of the facts in dispute in technical language, with instructions to the *iudex*. The part of the *formula* which contained the plaintiff's claim was called the *intentio*. Any equitable defence in the *formula* was set up by means of an *exceptio*, which was either peremptory, denying the right of the plaintiff to recover at all, or dilatory, denying only that the action could be brought at the time or by the particular plaintiff. The plaintiff might meet the *exceptio* with a *replicatio*, the defendant on his side might set up a *duplicatio*, and the plaintiff might traverse the *duplicatio* by a *triplicatio*. The parties might proceed even further, but beyond this point the pleadings had no special names. Actions *bonæ fidei* implied every *exceptio* that could be set up; in other actions the *exceptio* must be specially pleaded. From the *formula* the *iudex* derived his whole authority, and he was liable to an action for exceeding it. He could not amend the *formula*; that could only be done by the *prætor*. In the third period the *formula* did not exist, the plaintiff's claim appeared in the summons (*libellus conventionis*), and the defendant might take any defence that he pleased, all actions being placed on the footing of actions *bonæ fidei*. The issue to be tried was determined by the judge from the oral statements of the parties. In criminal procedure the indictment (*inscriptio* or *libellus accusationis*) was usually in writing, and contained a formal statement of the offence. In some cases oral accusations were allowed. The pleading of the accused seems to have been informal.

The development of the system of pleading in Roman and English law proceeded upon very similar lines. It is possible that the English system was directly based upon the Roman. Bracton (*temp.* Henry III.) uses many of the Roman technical terms. Pleading was oral as late as the reign of Henry VIII., but in the reign of Edward III. pleadings began to be drawn up in writing, perhaps at first more for the purpose of entry on the court records than of the instruction of the court (see 2 Reeves, *History of English Law*, 398). The French language was used up to 36 Edw. III. st. 1, c. 15, after which English was used for oral pleading, but Latin for enrolment. Latin was the language of written pleadings at common law until 4 Geo. II. c. 26.<sup>1</sup> Such terms as *declaration*, *answer*, *replication* are survivals of the oral period. It is no doubt from the circumstance of pleading having been originally oral that the word in the popular though not in the legal sense is used for the oral conduct of the case by an advocate.<sup>2</sup> The period of the Roman *formula* has its analogue in the period of the original writ in England.<sup>3</sup> The writ was at first a formal commission from the crown to a judicial officer to do justice between the parties, the claim being made by means of a count. The issue of the writ was part of the prerogative of the crown, unlimited until the Provisions of Oxford (1258) forbade the issue of fresh writs (except writs *de cursu*) without the consent of

<sup>1</sup> In Chancery the "English Bill," so called from its being in the English language, had existed long before this time,—according to Mr Spence, as early as the reign of Henry V. (*Equitable Jurisdiction*, vol. i. p. 348).

<sup>2</sup> In France *plaidier* and *plaidoyer* still bear this meaning.

<sup>3</sup> The original writ was so called to distinguish it from the judicial writ, which was a part of the process of the court. The judicial writs still exist, e.g., writs of *certiorari* or *feri facias*.

the council. Gradually the writ came to absorb the count and included the plaintiff's claim and sometimes the nature of his evidence. The defendant pleaded to the writ. The writ became the universal form of instituting proceedings in the king's court, irrespective of the method of trial which followed, and probably grew fixed in form about the reign of Henry II. (see Bigelow, *History of Procedure*, ch. iv.). At a later date the writ again tended to approach its earlier form and to split into two parts, the writ of summons and the declaration or plaintiff's claim. The writ of summons was addressed to the defendant, and not, as the original writ, to a judicial officer. The pleading became the act of the party, differing in this from Roman law, in which they were a judicial act. The writs became precedents for the forms of action, which, like the writs, were limited in number. The plaintiff's claim was a substantial repetition of the writ. Modern legislation, in the case of the specially indorsed writ of summons (see below), practically returns to this ancient stage of law. In the writ, as in the *formula*, the slightest failure in form was as a rule fatal. "The assigning of a writ of a particular frame and scope to each particular cause of action, the appropriating process of one kind to one action and of a different kind to another, these and the like distinctions rendered proceedings very nice and complex, and made the conduct of an action a matter of considerable difficulty" (1 Reeves, *Hist. of English Law*, 147). Fines were levied for mistakes in pleading, non-liability to which was sometimes granted by charter as a special privilege to favoured towns. In both Roman and English law fictions, equity, and legislation came to mitigate the rigour of the law. In England this result was largely attained by the framing of the action of trespass on the case under the powers of the Statute of Westminster the Second (13 Edw. I. stat. 1, c. 24), and by the extension of the action of *assumpsit* to non-feasance. To a less extent the same difficulties were found in the period of special pleading<sup>4</sup> which followed the writ period, owing to the particularity with which the claim had to be set out and the narrow powers of amendment possessed by the courts. The practical questions at issue were thrown into the shade by questions of the proper way of stating them. Substantive law could only be arrived at through the medium of adjective law. Special pleading became an art of the utmost nicety, depending on numerous rules, some of them highly technical (see Coke upon Littleton, 303). Those who made it their business to frame pleadings were called special pleaders. They were not necessarily members of the bar, but might be licensed to practise under the bar. Pleaders under the bar still exist, but recent legislation has much diminished their numbers and importance. Changes were gradually introduced by a long series of statutes of which the most important have been the Statutes of Jeofails, beginning as early as 14 Edw. III., c. 6, the Statutes of Set-off, the Common Law Procedure Acts, and the Judicature Acts. The advance has always been, as in Roman law, in the direction of less formality. Up to 1875 the system of pleading varied in the different courts which now compose the High Court of Justice. In the Common Law Courts the action was commenced by a *declaration* (containing either *special* or *common counts*, or both combined), to which the defendant put in a *plea* or pleas. The plea was either of the general issue, i.e., a bare denial (as "Never Indebted" to an action of debt), or special, setting out the facts with greater particularity. Pleas were also peremptory or dilatory, names taken from the Roman law.

<sup>4</sup> The ingenuity of the pleader chiefly showing itself in framing special as opposed to general pleas, the term special pleading grew to be used for the whole proceedings of which it was the most important part.

By the Common Law Procedure Act, 1854, equitable pleas might be pleaded. To the defendant's plea the plaintiff pleaded a *replication*; the defendant might follow with a *rejoinder*, the plaintiff with a *surrejoinder*, the defendant with a *rebutter*, the plaintiff with a *surrebutter*. Beyond that point, which was seldom reached, the pleadings had no special names. The pleadings concluded with a *joinder of issue*. A copy of the pleadings constituted the *record*. Since the Judicature Acts there has been no record, properly so called, in civil cases, though it has not been expressly abolished. Its place is supplied by copies of the pleadings delivered for the use of the judge and of the officer entering the judgment under the Rules of the Supreme Court, 1883 (Ord. xxxvi. r. 30; Ord. xli. r. 1). Either party might demur at any stage of the pleadings (see DEMURRER). In certain cases the replication of the plaintiff proceeded by way of *new assignment*; e.g., in an action of trespass to which justification was pleaded, the plaintiff might complain of acts in excess of those covered by the justification. In this case he was said to *new assign*, and the defendant pleaded to the new assignment. In the Court of Chancery the plaintiff's claim was contained in a *bill* (in certain matters of a public nature an *information*), to which the defendant filed an *answer* on oath or a *demurrer* or, more rarely, *pleas*, and the plaintiff a *replication*. Beyond the replication equity pleadings did not extend, the place of further pleadings being supplied by amendment. *Exceptions* (note again a Roman law term) might be taken to the bill or answer on various grounds. Equity pleadings, unlike common law pleadings, were signed by counsel.<sup>1</sup> In the High Court of Admiralty the pleadings were called *petition*, *answer*, *reply*, and *conclusion*. In the Court of Probate they were called *declaration*, *plea*, and *replication*, but the procedure was not the same as that in use in the Common Law Courts. In all the courts, a *special case* without pleadings could by leave of the court be stated for the opinion of the court.

The Judicature Act, 1873, introduced a uniform system of pleading in the High Court of Justice. The practice is now regulated by the Rules of the Supreme Court, 1883. By Ord. xix. r. 4, "every pleading shall contain, and contain only, a statement in a summary form of the material facts on which the party pleading relies for his claim or defence, as the case may be, but not the evidence by which they are to be proved, and shall, when necessary, be divided into paragraphs, numbered consecutively. Dates, sums, and numbers shall be expressed in figures and not in words. Signature of counsel shall not be necessary; but where pleadings have been settled by counsel or a special pleader they shall be signed by him, and if not so settled they shall be signed by the solicitor or by the party if he sues or defends in person." The term "pleading" in the Judicature Acts includes a petition or summons, 36 & 37 Vict. c. 66, § 100. From 1875 to 1883 the plaintiff had in almost every case to deliver a *statement of claim*. But now no statement of claim is delivered where the action is commenced by a specially indorsed writ, or where the writ is not specially indorsed unless the defendant gives notice in writing that he requires a statement of claim to be delivered.<sup>2</sup> The defendant presents his case in a *statement of defence*, and may also *set off* or set up by way of *counter-claim* any right or claim against the plaintiff whether sounding in damages or not. A counter-claim

may be made against the plaintiff and a third party. To a statement of defence or counter-claim the plaintiff or third party delivers a *reply*. No pleading other than a joinder of issue can be pleaded after reply except by leave of the court or a judge. Both the parties and the court or a judge have large powers of amending the pleadings. Issues are in certain cases settled by the court or a judge. Demurrers are abolished, and a party is now entitled to raise by his pleading any point of law. Forms of pleadings are given in Appendices C, D, and E to the Rules of 1883. In actions for damages by collision between ships, a document called a *preliminary act* (before the Judicature Act peculiar to the Court of Admiralty) must be filed, containing details as to the time and place of collision, the speed, tide, lights, &c. The case may be tried on the preliminary act without pleadings. In all actions such ground of defence or reply as if not raised would be likely to take the opposite party by surprise, or would raise issues of fact not arising out of the preceding pleadings, must be specially pleaded. Such are compulsory pilotage, fraud, the Statute of Limitations, the Statute of Frauds. The pleadings in *replevin* and *petition of right* are governed by special rules. To courts other than the High Court of Justice the Judicature Acts do not apply. In some courts, however, such as the Chancery of the County Palatine of Lancaster and the Court of Passage of the City of Liverpool, the rules of pleading used in the High Court have been adopted with the necessary modifications. In the Mayor's Court of London the common law pleading, as it existed before the Judicature Acts, is still in use. In the ecclesiastical courts the statements of the parties are called generally *pleas*. The statement of the plaintiff in civil suits is called a *libel*, of the promoter in criminal suits *articles*. Every subsequent plea is called an *allegation*. To the responsive allegation of the defendant the promoter may plead a counter-allegation. The cause is concluded when the parties renounce any further allegation. In the Divorce Court the pleadings are named *petition*, *answer*, *replication*. In that court and in the ecclesiastical courts there exists in addition a more short and summary mode of pleading called an *act on petition*. In the county courts proceedings are commenced by a *plaint*, followed by an *ordinary* or *default summons*. No further pleadings are necessary, but the defendant cannot set up certain special defences, such as set-off or infancy, without the consent of the plaintiff, unless after notice in writing of his intention to set up the special defence.

The pleading in English criminal law has been less affected by legislation than the pleading in actions. The pleading is more formal, and oral pleading is still retained. Cases in which the crown was a party early became known as pleas of the crown (*placita coronæ*), as distinguished from common pleas (*communia placita*), or pleas between subject and subject, that is to say, ordinary civil actions. Pleas of the crown originally included all matters in which the crown was concerned, such as exchequer cases, franchises, and liberties, but gradually became confined to criminal matters, strictly to the greater crimes triable only in the king's courts. In criminal pleading the crown states the case in an *indictment* or *information*. The answer of the accused is a *plea*, which must in almost all cases be pleaded by the accused in person. The plea, according to Blackstone, is either to the jurisdiction, a demurrer, in abatement, special in bar, or the general issue. The latter is the only plea that often occurs in practice; it consists in the oral answer of "Guilty" or "Not Guilty" to the charge. A demurrer is strictly not a plea at all, but an objection on legal grounds. Pleas to the jurisdiction or in abatement do not go to the merits of the case, but allege that the court has no jurisdiction to

<sup>1</sup> For the pleading before 1875 see Stephen on *Pleading* for the Common Law Courts, *Story on Equity Pleading* for the Court of Chancery, and the articles BILL and DECLARATION.

<sup>2</sup> A specially indorsed writ may be used in an action for a debt or liquidated demand. The advantage of using it is that the defendant must obtain leave to defend the action by showing to the satisfaction of a judge that he has reasonable grounds of defence.

try the particular offence, or that there is a misnomer or some other technical ground for stay of proceedings. The power of amendment and the procedure by motion in arrest of judgment have rendered these pleas of little practical importance. The special pleas in bar are *autrefois convict* or *autrefois acquit* (alleging a previous conviction or acquittal for the same crime), *autrefois attain* (practically obsolete since the Felony Act, 1870, has abolished attainder for treason or felony), and pardon (see PARDON). There are also special pleas in indictments for libel under the provisions of Lord Campbell's Act, 6 & 7 Vict. c. 96 (see LIBEL), and to indictments for non-repair of highways and bridges, where the accused may plead that the liability to repair falls upon another person. These special pleas are usually, and in some cases must be, in writing. Where there is a special plea in writing, the crown puts in a *replication* in writing. (For the history of criminal pleading see Stephen, *History of the Criminal Law*, vol. i. ch. ix.)

In Scotland an action in the Court of Session begins by a *summons* on the part of the pursuer to which is annexed a *condescendence*, containing the allegations in fact on which the action is founded. The *pleas in law*, or statement of the legal rule or rules relied upon (introduced by 6 Geo. IV. c. 120, § 9), are subjoined to the condescendence. The term *libel* is also used (as in Roman law) as a general term to express the claim of the pursuer or the accusation of the prosecutor. The statement of the defender, including his pleas in law, is called his *defences*. They are either dilatory or peremptory. There is no formal joinder of issue, as in England, but the same end is attained by adjustment of the pleadings and the closing of the record. Large powers of amendment and revival are given by the Court of Session Act, 1868. In the Sheriff Court pleadings are very similar to those in the Court of Session. They are commenced by a *petition*, which includes a condescendence and a note of the pursuer's pleas in law. The defender may upon notice lodge defences. The procedure is now governed by 39 & 40 Vict. c. 70. The term "pleas of the crown" is confined in Scotland to four offences—murder, rape, robbery, and fire-raising. A prosecution is commenced either by *indictment* or *criminal letters*, the former being the privilege of the lord advocate. In the Supreme Court the indictment or criminal letters run in the name of the lord advocate; in the Sheriff Court the criminal letters (indictments not being used in that court) run in the name of the judge. The Scotch indictment differs from the English, and is in the form of a syllogism, the major proposition stating the nature of the crime, the minor the actual offence committed and that it constitutes the crime named in the major, the conclusion that on conviction of the panel he ought to suffer punishment. The panel usually pleads "Guilty" or "Not Guilty" as in England, but he may plead in bar want of jurisdiction or *res judicata*, or make special defences (such as *alibi* or insanity), which must be lodged with the clerk of the court in writing signed by him or his counsel. The special defences is read to the jury immediately after they have been sworn. (See Macdonald, *Criminal Law of Scotland*.)

In the United States two systems of pleading in civil procedure exist side by side. Up to 1848 the pleading did not materially differ from that in use in England at the same date. But in 1848 the New York legislature made a radical change in the system, and the example of New York has been followed by more than twenty States. The New York Civil Code of 1848 established a uniform procedure called the civil action, applicable indifferently to common law and equity. The pleadings are called *complaint*, *answer* (which includes *counterclaim*), and *reply*. The *demurrer* also is still used. In some States which follow the new procedure the complaint bears the name of *petition*. In the inferior courts, such as courts of justices of the peace, the pleadings are more simple, and in many cases oral. In States which do not adopt the amended procedure, the pleading is much the same as it was in the days of Blackstone, and the old double jurisdiction of common law and equity still remains. Criminal pleading differs little from that in use in England. (See Bishop, *Law of Criminal Procedure*.)

(J. Wt.)

**PLEBEIANS.** See NOBILITY and ROME.

**PLEDGE, or PAWN,** in law, is "a bailment of personal property as a security for some debt on engagement" (Story on *Bailments*, § 286). The term is also used to denote the property which constitutes the security. Pledge is the *pignus* of Roman law, from which most of the law on the subject is derived. It differs from the mortgage, which still exists, e.g., from the more usual kind of mortgage in

that the pledge is in the possession of the pledgee; it also differs from mortgage in being confined to personal property. A mortgage of personal property in most cases takes the name and form of a bill of sale (see BILL, the giving of bills of sale being now regulated by the Bills of Sale Acts, 1878 and 1882). The chief difference between Roman and English law is that certain things, e.g., wearing apparel, furniture, and instruments of tillage, could not be pledged in Roman law, while there is no such restriction in English law. In the case of a pledge, a special property passes to the pledgee, sufficient to enable him to maintain an action against a wrongdoer, but the general property, that is the property subject to the pledge, remains in the pledgor. As the pledge is for the benefit of both parties, the pledgee is bound to exercise only ordinary care over the pledge. The pledgee has the right of selling the pledge if the pledgor make default in payment at the stipulated time. No right is acquired by the wrongful sale of a pledge except in the case of property passing by delivery, such as money or negotiable securities. In the case of a wrongful sale by a pledgee, the pledgor cannot recover the value of the pledge without a tender of the amount due. For pledges by factors see FACTOR. A pledge by a banker, merchant, broker, attorney, or other agent, in violation of good faith, and contrary to the purpose for which the property pledged was intrusted to him, or a pledge of property with which he was intrusted for safe custody, renders the offender guilty of a misdemeanor, punishable with a maximum term of seven years' penal servitude, 24 & 25 Vict. c. 96, §§ 75, 76. Pledges with pawnbrokers are regulated by the Pawnbrokers' Act, 1872, 35 & 36 Vict. c. 93 (which applies to Great Britain). By the provisions of the Act (which does not affect loans above £10), a pledge is redeemable within one year and seven days of grace added to the year. Pledges pawned for 10s. or under not redeemed in time become the property of the pawnbroker, pledges above 10s. are redeemable until sale. The sale must be by public auction. The pawnbroker is entitled to charge as interest one halfpenny per month on every two shillings lent where the loan is under 40s., on every two shillings and sixpence where the loan is above 40s. Special contracts may be made where the loan is above 40s. Unlawful pawning of goods not the property of the pawner, and taking in pawn any article from a person apparently under the age of sixteen or intoxicated, or any linen or apparel or unfinished goods or materials intrusted to wash, make up, &c., are (*inter alia*) made offences punishable by summary conviction. An annual licence, costing £7, 10s., must be taken out for every pawnbroker's shop.

The law of Scotland as to pledge generally agrees with that of England, as does also that of the United States. The main difference is that in Scotland and Louisiana a pledge cannot be sold unless with judicial authority. In some of the States the common law as it existed apart from the Factors' Acts is still followed; in others the factor has more or less restricted power to give a title by pledge. In some States pawnbroking is regulated by the local authorities, and not, as in most, by the general law of the State.

**PLESIOSAURIANS.** The remarkable extinct marine reptiles included in the group of the *Plesiosauria* (or *Sauropterygia*, as they are sometimes called) existed during the whole of the Mesozoic period, that is, from Triassic into Cretaceous times, when they appear to have died out. The best known of these reptiles, and that which gives its name to the group is the *Plesiosaurus*, a genus established by Conybeare in 1821, and including numerous species, some of which may have attained a length of as much as 20 feet. The nearly allied *Elasmosaurus* of North America, however, reached a much greater size, its remains indicating an animal about 45 feet in length. Several almost perfect skeletons of *Plesiosaurus* having at

different times been found, the general proportions of the body are well known. Although the different species vary in regard to proportions, the small size of the head and extreme length of the neck are always striking points in the skeleton of a *Plesiosaurus*, while the tail is proportionately short. The limbs, both fore and hind, are well developed and modified for swimming, the forms of the various bones making it clear that the digits of each limb were not separate, but enclosed in one covering of integument, as in the flippers of a whale or a turtle. The exterior of the body, there is every reason to believe, was smooth as it is in *Cetacea*, and not provided with either

bony or horny scutes or scales as in the living crocodiles and turtles. The internal skeleton therefore is the only part available for study.

The skull of *Plesiosaurus* has a tapering and depressed snout, and in consequence of the large size of the premaxillary bones the nasal apertures are placed far back, just in front of the orbit, as in birds. There is a distinct parietal foramen, as in lizards. The orbit is completely surrounded by bone, and there are supra- and infra-temporal fossæ. The single occipital condyle is formed almost entirely by the basi-occipital bone. The basi-sphenoid is well developed, and is produced into a long

FIG. 1.—*Plesiosaurus* (after Owen).

rostrum. On the base of the skull four fossæ are to be seen; the front pair of these are bounded behind by the palatine bones, and are regarded as the true posterior nares. The teeth are slender, sharp, curved, and striated; they have single fauga, and are placed loosely in separate alveolar sockets.

The spinal column is composed of a large number of vertebrae, some species having ninety or more in the entire series. The centrum of each vertebra has the fore and hind surfaces slightly concave; the neural arch is connected with the centrum by a suture, which seems never to have been entirely obliterated. The cervical vertebrae vary in number from twenty-four to upwards of forty in different species. Each is provided with a pair of ribs, closely resembling those found in the cervical region in the crocodile, but with a single articular head only. Towards the hinder part of the neck the ribs become more elongated, and take on the form of dorsal ribs; but, as none of the ribs join the sternum, the usual means of distinguishing the dorsal and cervical regions is wanting. There may be from twenty to thirty dorsal vertebrae. True sternal ribs have never been detected; but abdominal

front and outside of which is a peculiarly shaped scapula with a plate extending dorsally from the glenoid cavity, and a second process directed inwards and downwards. The latter process is now regarded as the precoracoid by Mr J. W. Hulke, who also considers the plate of bone—originally of two pieces—found in the middle and in front of the coracoids to be the homologue of the omosternum of *Batrachia*. If this

interpretation be correct, *Plesiosaurus* has neither clavicles nor interclavicles. In the fore limb all the characteristic bones are present. The humerus is an elongated bone with the anterior border nearly straight and the hinder border concave; it is rounded at the upper end, and flattened below, where it is articulated to two much shorter bones, the radius and ulna. Next to these is a row of three carpal bones—the radiale (scaphoid), the ulnare (cuneiform), and the intermedium (lunar); a second row of four bones succeeds these, three of which are carpals, but the outer one may be a metacarpal; next comes a row of five metacarpals. The digits are five in number, and with the exception of the first are made up of numerous separate ossicles, or phalanges.

The pelvic arch (fig. 3) is large, and ventrally consists of a pair of flattened more or less quadrate pubes, and a pair of somewhat triangular ischia. The iliac bones are elongated, narrower where they form part of the acetabular articulation and becoming broader above where they join the sacral ribs. The hind limb very closely resembles the fore limb. The front and back margins of the femur are straighter than they are in the humerus; but the other parts almost exactly repeat the corresponding bones of the fore limb.

With regard to the probable habits of the *Plesiosaurus* we are not without some indications. The paddle-like form of the limbs leaves no doubt as to its aquatic mode of life, and judging from the fossils with which it is usually associated it must have been an inhabitant of the sea; it is highly probable, however, that some species at least ascended rivers, for remains of *Plesiosauria* are found in the Wealden freshwater deposits. The comparatively small tail and large paddles render it probable that the limbs were the chief means of propulsion. The long neck would tend to impede its progress through the water, and it would be better adapted, therefore, for swimming on or near the surface. It is unlikely that the *Plesiosaurus* could move as rapidly through the water as the *Ichthyosaurus*; but this slower movement would be compensated for by the rapidity with which its long and flexible neck could be darted at its prey. Seeing that the marine turtles and seals of the present day make their way on shore, it is quite possible that the *Plesiosaurus* may also have occasionally visited the

FIG. 2.—Pectoral arch of *Plesiosaurus*, seen from below (after Hulke). co, coracoid; sc, scapula; pc, precoracoid; ost, omosternum.

Fig. 3.

FIG. 3.—Pelvic arch of *Plesiosaurus*, from above (after Huxley). is, Ischium; pb, pubis; il, Ilium.

bones, or ribs, are well developed. The sacrum consists of two vertebrae, with stout broad ribs for attachment to the iliac bones. The caudal vertebrae, between thirty and forty in number, have distinct chevron bones, which are attached between the successive vertebrae. The pectoral arch (fig. 2) consists of a large coracoid on each side, in

land. The sharp and slender teeth would be admirably adapted for catching and holding a slippery prey, and there is no doubt that fishes formed in part, if not altogether, its natural food. Indeed the scales and teeth of fishes have been found, in one case at least, just below the vertebrae, in the region which must have been occupied by the creature's stomach.

It is of interest to note the differences which exist between the *Platysaurus* and the *Ichthyosaurus* (g.n.), the latter being the type of another group, the *Ichthyosaurus*, which is by some palaeontologists included with the *Platysaurus* in a larger group called *Enaliosaurus*. In outward form the *Ichthyosaurus* must have resembled some of the recent *Cetaceæ*, inasmuch as the head is proportionately large, and without any appearance of a neck joins directly on to the trunk. The hind limbs are smaller than the front ones, and the bones of both limbs are much more shortened and flattened than in *Platysaurus*; in addition to this there are supernumerary rows of bones, besides the five typical digital series. The pectoral arch differs in having distinct clavicles and interclavicles. The vertebrae are short from back to front, deeply bilobed, and their neural arches never have a bony connexion with the centra. There is no sacrum. The teeth are placed in a groove, and not in separate sockets. The eye-ball was protected by a series of bony sclerotic plates, which are not found in *Platysaurus*.

The group *Platysaurus* includes several other genera besides the *Platysaurus*; but most of these are only represented by such imperfect specimens that the distinctions between them, as at present known, are far from satisfactory. The characters which have been relied upon for their separation are to be found chiefly in the structure of the pectoral arch, limbs, and vertebrae. *Platysaurus* is only certainly known to have existed from the time of the Lower Lias to the Cretaceous; and it is especially characteristic of the Lias. More than fifty species, sometimes placed in several subgenera, have been described from different localities in Britain, some of which are represented by remarkably perfect specimens, and others by fragments only. This genus has a wide geographical distribution, species having been named from Secondary strata, on the continent of Europe, in India, Australia, South America, and North America. The closely allied and gigantic form *Platysaurus* is chiefly characteristic of the English Oolites.

In European Triassic beds, *Platysaurus* are represented by such genera as *Mithrasaurus*, *Stenosaurus*, and *Plesiosaurus*, in all of which the neural arches seem to have been less closely united to the vertebral centra than in *Platysaurus*. *Neustrosaurus* is another Triassic form, remarkable, not only on account of its small size, being less than 12 inches in length, but also because its limbs seem to show a transitional condition: for, while the structure of the hind limb resembles that of a land reptile, the fore limb seems to have had more the structure of a paddle.

A number of forms closely related to the *Platysaurus* have been described from rocks of Cretaceous age in North America under the following generic names—*Cimoliasaurus*, *Elassmosaurus*, *Oligosaurus*, *Forsthausia*, and *Polyotylus*. Of these the *Elassmosaurus* is better known than any of the others. It was an extremely elongated form, as may be gathered from the fact that the snake-like neck alone consisted of more than sixty vertebrae—the entire body, as we have noticed above, being more than 45 feet in length.

**PLETHO.** See **GEMISTO**.

**PLEURISY**, or **PLEURITIS**, inflammation of the pleura or serous membrane investing the lungs and lining the interior of the thoracic cavity. It is a common form of chest complaint, and may be either acute or chronic, more frequently the former.

The morbid changes which the pleura undergoes when inflamed are similar to those which take place in other serous membranes, such as the peritoneum (see **PERITONITIS**), and consist of three chief conditions or stages of progress. (1) Inflammatory congestion and infiltration of the pleura, which may spread to the tissues of the lung on the one hand, and to those of the chest wall on the other. (2) Exudation of lymph on the pleural surfaces. This lymph is of variable consistence, sometimes composed of thin and easily separated pellicles, or of extensive thick masses or strata, or again showing itself in the form of a tough membrane. It is of greyish-yellow colour, and

microscopically consists mainly of coagulated fibrine along with epithelial cells and red and white blood corpuscles. Its presence causes roughening of the two pleural surfaces, which, slightly separated in health, may now be brought into contact by bands of lymph extending between them. These bands may break up or may become organized by the development of new blood-vessels, and adhering permanently may obliterate throughout a greater or less space the pleural sac, and interfere to some extent with the free play of the lungs. (3) Effusion of fluid into the pleural cavity. This fluid may vary in its characters. Most commonly it is clear or slightly turbid, of yellowish-green colour, sero-fibrinous, and containing flocculi of lymph. In bad constitutions or in cases where the pleurisy complicates some severe form of disease, e.g., the acute infectious maladies, it is deeply coloured, bile-stained, sero-purulent, purulent, or bloody, occasionally containing bubbles of air from decomposition. The amount may vary from an almost inappreciable quantity to a gallon or more. When large in quantity it may fill to distension the pleural sac, bulge out the thoracic wall externally, and compress more or less completely the lung, which may in such cases have all its air displaced and be reduced to a mere fraction of its natural bulk lying squeezed up upon its own root. Other organs, such as the heart and liver, may in consequence of the presence of the fluid be shifted away from their normal position. In favourable cases the fluid is absorbed more or less completely and the pleural surfaces again may unite by adhesions; or, all traces of inflammatory products having disappeared, the pleura may be restored to its normal condition. When the fluid is not speedily absorbed it may remain long in the cavity and compress the lung to such a degree as to render it incapable of re-expansion as the effusion passes slowly away. The consequence is that the chest wall falls in, the ribs become approximated, the shoulder is lowered, the spine becomes curved and internal organs permanently displaced, while the affected side scarcely moves in respiration. Sometimes the unabsorbed fluid becomes purulent, and an *empyema* is the result. In such a case the matter seeks vent in some direction, and it may point as an abscess upon the chest or abdominal wall, or on the other hand burst into the lung and be discharged by the mouth. It must be observed that many cases of pleurisy do not reach the stage of effusion, the inflammation terminating with the exudation of lymph. To this form the term *dry pleurisy* is applied. Further pleurisy may be limited to a very small area, or, on the contrary, may affect throughout a greater or less extent the pleural surfaces of both lungs.

Pleurisy frequently arises from exposure to cold; hence it is more common in the colder weather; but besides this various other causes are connected with its occurrence. Thus it is often associated with other forms of disease within the chest, more particularly pneumonia, bronchitis, and phthisis, and also occasionally accompanies pericarditis. Again it is apt to occur as a secondary disease in certain morbid constitutional states, e.g., the infectious fevers, rheumatism, gout, Bright's disease, diabetes, &c. Further, wounds or injuries of the thoracic walls are apt to set up pleurisy, and the rupture of a phthisical cavity in the lungs causing the escape of air and matter into the pleura has usually a similar effect.

The symptoms of pleurisy vary, being generally well-marked, but sometimes obscure. In the case of dry pleurisy, which is on the whole the milder form, the chief symptom is a sharp pain in the side, felt especially in breathing. Fever may or may not be present. There is slight dry cough; the breathing is quicker than natural, and is shallow and of catching character. If much pain is present the body leans somewhat to the affected side, to

relax the tension on the intercostal muscles and their covering, which are even tender to touch. On listening to the chest by the stethoscope the physician recognizes sooner or later "friction," a superficial rough rubbing sound, occurring only with the respiratory acts and ceasing when the breath is held. It is due to the coming together during respiration of the two pleural surfaces which are roughened by the exuded lymph. The patient may himself be aware of this rubbing sensation, and its vibration or fremitus may be felt by the hand laid upon the thoracic wall during breathing. This form of pleurisy may be limited or may extend over the greater part of one or both sides. It is a not unfrequent complication of phthisis in all its stages. In general it disappears in a short time, and complete recovery takes place; or on the other hand extensive adhesions may form between the costal and pulmonary surfaces of the pleura, preventing uniform expansion of the lung in respiration, and leading to emphysema. Although not of itself attended with danger, dry pleurisy is sometimes preliminary to more serious lung disease, and is always therefore to be regarded while it lasts with some degree of anxiety.

*Pleurisy with effusion* is usually more severe than dry pleurisy, and, although it may in some cases develop insidiously, it is in general ushered in sharply by rigors and fever, like other acute inflammatory diseases. Pain is felt in the side or breast, of a severe cutting character, referred usually to the neighbourhood of the nipple, but it may be also at some distance from the affected part, such as through the middle of the body or in the abdominal or iliac regions. This transference of the pain occasionally misleads the medical examiner. The pain is greatest at the outset, and tends to abate as the effusion takes place. A dry cough is almost always present, which is particularly distressing owing to the increased pain the effort excites. The breathing is painful and difficult, tending to become shorter and shallower as the disease advances and the lung on the affected side becomes compressed. The patient at first lies most easily on the sound side, but as the effusion increases he finds his most comfortable position on his back or on the affected side. When there is very copious effusion and, as is apt to happen, great congestion of the other lung, or disease affecting it, the patient's breathing may be so embarrassed that he cannot lie down.

On physical examination of the chest the following are among the chief points observed. (1) On inspection there is more or less bulging of the side affected, obliteration of the intercostal spaces, and sometimes elevation of the shoulder. (2) On palpation with the hand applied to the side there is diminished expansion of one-half of the thorax, and the normal vocal fremitus is abolished. Should the effusion be on the right side and copious, the liver may be felt to have been pushed downwards, and the heart somewhat displaced to the left; while if the effusion be on the left side the heart is displaced to the right. (3) On percussion there is absolute dulness over the seat of the effusion. If the fluid does not fill the pleural sac the floating lung may yield a hyper-resonant note. (4) On auscultation the natural breath sound is inaudible over the effusion. Should the latter be only partial the breathing is clear and somewhat harsh, with or without friction, and the voice sound is ægophonic. Posteriorly there may be heard tubular breathing with ægophony. These various physical signs render it impossible to mistake the disease for other maladies the symptoms of which may bear a resemblance to it, such as pleurodynia.

The absorption or removal of the fluid is marked by the disappearance or diminution of the above-mentioned physical signs, except that of percussion dulness, which

may last a long time, and is probably due in part to the thickened pleura. Friction may again be heard as the fluid passes away and the two pleural surfaces come together. The displaced organs are restored to their position, and the compressed lung re-expanded. Frequently this expansion is only partial, and consequently, as already indicated, the chest falls in, the respiration on one side is imperfectly performed, and the patient remains permanently short in breathing to a greater or less degree.

In most instances the termination is favourable, the acute symptoms subsiding and the fluid (if not drawn off) gradually or rapidly becoming absorbed, sometimes after re-accumulation. On the other hand it may remain long without undergoing much change, and thus a condition of *chronic pleurisy* becomes established. Such cases are to be viewed with suspicion, particularly in those who are predisposed to phthisis, of which it is sometimes the precursor.

Pleurisy may exist in a latent form, the patient going about for weeks with a large accumulation of fluid in his thorax, the ordinary acute symptoms never having been present in any marked degree. Cases of this sort are often protracted, and their results unsatisfactory as regards complete recovery.

The chief dangers in pleurisy are the occurrence of a large and rapid effusion, particularly if both sides be affected, causing much embarrassment to the breathing and tendency to collapse; the formation of an empyæma (often marked by recurring rigors and hectic symptoms); severe collateral congestion of the other lung; imperfect recovery; and the supervention of phthisis. Further the consequences are apt to be more serious where pleurisy exists as a complication of some pre-existing disease.

The treatment of pleurisy need only be alluded to in general terms. It will necessarily depend as regards details upon the form and severity of the attack. One of the first symptoms calling for treatment is the pain. Opiates in the form of morphia or Dover's powder are useful along with the application to the chest of hot poultices or fomentations sprinkled with turpentine. In severe cases much relief to the pain and difficulty of breathing may be afforded by the application of a few leeches to the side. Cases of simple dry pleurisy usually soon yield to such treatment, aided if need be by the application of a fly-blister or of iodine to the chest. The fixing as far as possible of the one side of the thorax by means of cross straps of adhesive plaster according to the plan recommended by Dr Roberts seems of use in many instances. In the case of pleurisy with effusion, in addition to these measures, including blistering, the internal use of saline cathartics and diuretics appears to be often of service in diminishing the amount of the fluid in the pleural cavity, as are also powerful diaphoretics such as pilocarpin. When these measures fail to reduce the effusion the question of the artificial removal of the fluid comes to be considered. The operation (thoracentesis) was practised by the ancient physicians, but was revived in modern times by Trousseau in France and Bowditch in America, by the latter of whom an excellent instrument was devised for emptying the chest, which, however, has been displaced in practice by the still more convenient aspirator. The propriety of this proceeding in pleurisy with effusion has been much discussed, but there now appears to be a general consent that in cases of extensive accumulation, when other means such as those briefly referred to fail to reduce or remove the fluid in a short time, the only hope of preventing such compression of the lung as will impair its function lies in the performance of thoracentesis. All the more will the operation be justifiable if the accumulated fluid is interfering with the function of other organs, such as the heart, or is attended with marked embarrassment of the breathing. The chest is punctured in the lateral or posterior regions, and in most cases the greater portion or all of the fluid may be safely drawn off. In general the operation is unattended with danger, although not entirely exempt from such risks as sudden syncope, and therefore not to be undertaken without due vigilance as well as a careful consideration of the individual case and its associations. In many instances not only is the removal of distressing symptoms speedy and complete, but the lung is relieved from pressure in time to enable it to resume its normal function. When there is any evidence that the fluid is purulent the operation should be performed early. In such cases it is sometimes necessary to establish for a time a drainage of the pleural cavity by surgical measures.

The convalescence from pleurisy requires careful tending, and the state of the chest should be inquired into from time to time, in view of the risks of more serious forms of lung disease supervening.

(J. O. A.)

PLEURO-PNEUMONIA. See MURRAY, vol. xvii. p. 60.

PLEVNA, or PLEVEN, the chief town of one of the provinces in the principality of Bulgaria, lies in the midst of a series of hills (whose crests rise above it for 200 to 600 feet) and about 6000 yards to the east of the river Vid (a tributary of the Danube), into which the streamlets by which it is traversed discharge. Its position at the meeting place of roads from Widdin, Sofia, Shipka, Biela, Zimnitsa, and Nikopoli gives it a certain military importance, and in the Russian campaign of 1877 it became one of the great centres of operation. The Russians, who had been defeated in two minor attacks on the 20th and 30th of July, were again repulsed with a loss of 18,000 men in an assault (September 7-13) in which they employed 75,000 infantry and 60,000 cavalry. They formally invested the town on October 24th and obliged Osman Pasha to surrender on December 10th. In 142 days the assailants had lost 40,000 men and the defenders 30,000. Plevna, which contains two old Christian churches as well as a number of mosques, had 11,129 inhabitants in 1881, the province at the same date containing 100,870.

See F. V. Greene, *The Russian Army and its Campaigns in Turkey in 1877-78*, London, 1879.

PLEYEL, IGNAZ JOSEPH (1757-1831), though now almost forgotten, was once one of the most popular composers in Europe. He was born at Ruppersthal, near Vienna, June 1, 1757, studied the pianoforte under Van Hal (known in England as Vanhall), and learned composition from Haydn, who became his dearest friend. He was appointed maître de chapelle at Strasburg in 1783; and in 1791 he was invited to London, where, though Haydn was also there, he achieved an immense success. On his return to Strasburg he narrowly escaped the guillotine; but, after proving that he was not an aristocrat, he was permitted to remain until 1795, when he migrated to Paris. Here he opened a large music shop, published the first complete edition of Haydn's quartets, and founded, in 1807, the pianoforte manufactory which still bears his name. He died at Paris, November 14, 1831.

Pleyel's compositions are very numerous, but it is only in the earlier ones that the fire of true genius is discernible. His daughter-in-law, Maria Pleyel,—née Moke (1811-1875), and wife of his eldest son, Camille,—was one of the most accomplished pianists of the age.

PLINY, THE NATURALIST (23-79 A.D.). Caius Plinius Secundus, commonly distinguished as the elder Pliny, the author of the *Natural History*, is believed to have been born (23 A.D.) at Novum Comum (Como). In the first sentence of his preface he calls Catullus, born at Verona, "conterraneum meum," meaning, perhaps, a native of Gallia Cisalpina, though it may be that Verona was the actual birthplace of both.<sup>1</sup> At Comum, however, was the family estate which the younger Pliny inherited from his uncle. Like his nephew, the elder Pliny had seen military service, having joined the campaign in Germany under L. Pomponius Secundus;<sup>2</sup> like him also, he had been a pleader in the law-courts, and a diligent student of Greek and Roman literature. Much of his literary work was done, he tells us himself, in the hours stolen from sleep. Of his many works the *Naturalis Historia* in thirty-seven books has alone been preserved, and in a nearly complete state. This voluminous treatise professes to be an encyclopædia of Roman knowledge, mainly based on the researches and speculations of the Greeks. What A. von Humboldt

accomplished in our own times, in his great work *Cosmos*, Pliny had essayed to carry out on similar principles;—but, of course, without the scientific knowledge, and also without the comprehensive view of the universe which is the inheritance of the present age. Pliny, we must admit, was an industrious compiler, but he was not, like Aristotle, a man of original research.<sup>3</sup>

In his first book, which contains a summary of the whole work, he names the authors, both Greek and Latin, from which the matter of each book was derived.<sup>4</sup> The list indeed is a surprising one, and of comparatively few have we any remains. Among Roman authors he most frequently cites Cato the censor, M. Varro, Celsus, Cornelius Nepos, Pomponius Mela, Columella; among the Greeks, Aristotle, Theophrastus, Democritus, more than one Apollodorus, Apollonius of Pergamum, and Hippocrates. The Latin writers he calls simply "auctores;" the Greeks, of whom the list is considerably longer, are "externi."

The preface, written in a rather inflated and by no means clear style, very inferior to the Latinity of the younger Pliny, is a dedication of the work in a strain of extravagant adulation to Titus, who was then, as Caesar, joint emperor with his father Vespasian. Pliny apologizes for dedicating to such a man a work of such commonplace and hackneyed subject-matter, but he pleads the novelty of the undertaking, and boasts of being the first who had attempted so comprehensive a theme.

The work itself commences with a pantheistic definition of the universe, *Mundus*, i.e., world and sky, and the sun and stars in space. This, he says, is reasonably regarded as a divinity—eternal, boundless, uncreated, and indestructible. Nature, he adds, and Nature's work are one, and to suppose there is more than one universe is to believe there can be more than one Nature,—which he calls "furor." His theology is "agnostic," or Epicurean; if there is any God, he says, it is vain to inquire His form and shape; He is entirely a Being of feeling and sentiment and intelligence, not of tangible existence. He believes in the "religion of humanity," according to a rather recent definition of the idea. God is what Nature is; God cannot do what Nature cannot do; He cannot kill Himself, nor make mortals immortal, nor raise the dead to life, nor cause one who has lived never to have lived at all, or make twice ten anything else than twenty. The last sentence of his work is remarkable, and is characteristic of a pagan piety which takes Nature alone for its God:—"Salve, parens rerum omnium Natura, teque nobis Quiritium solis celebratum esse numeris omnibus tuis fave" (xxxvii. 205).

But, although he regarded nature as one whole, of the great doctrine of the unity of nature and the tendency of all its operations to one definite end Pliny had no correct idea. He had a great store of ill-digested knowledge, not only imperfect in itself, but put together on no consistent plan. His style too is forced and somewhat pedantic, so that to read through and understand even a single book is by no means a light task.

To give an outline sketch of the *Natural History*, it may be said that book ii. treats of earth, stars, meteorics, and terrestrial phenomena, such as earthquakes, elevation of islands, &c. Books iii. to vi. inclusive are devoted to a geographical account of the known

<sup>3</sup> He claims for himself "ingenium perquam mediocre," *Præf.* § 12. His nephew (iii. 5, § 8) calls it "acre ingenium," which may mean active and energetic.

<sup>4</sup> Hence he reckons the number of books at 36, the subject beginning with Book ii. The matter of these, he says, comprising 20,000 points worthy of attention, he has collected from the perusal of about 2000 books, and from 100 Roman authors of special note (ex exquisitis auctoribus centum), *Præf.* § 17. The first book the author regards as an appendix to the dedicatory letter or preface, "Quia occupationibus tuis publico bono parcendum erat, quid singulis contineretur libris huic epistolæ subjuncti," *Præf.* § 33.

<sup>1</sup> But, as has been shrewdly remarked by Mr Long, "this somewhat barbarous word is much better adapted to intimate that Catullus was a fellow-countryman of Pliny than that he was a fellow-townsmen."

<sup>2</sup> "De Vita Pomponii Secundi duo (libri)" are enumerated among his uncle's works by the younger Pliny, *Ep.* iii. 5, § 3, who adds, "a quo singulariter amatus hoc memorize amici quasi debitum munus exsolvit."

world, in giving which the author makes no mention of Strabo. Book vii. contains a physical treatise on man, his form, the laws of his birth, age, mental qualities, &c. Book viii. treats of the larger beasts, as elephants, lions, tigers, camels, descending to snakes, crocodiles, and the smaller and domesticated animals. Book ix. includes marine animals of all kinds, fishes, shells, crustaceans, sponges, &c. Book x. is on birds, xi. on insects,—the latter half being devoted to an anatomical description of animals generally. Book xii. is on trees; xiii. on their products, fruit, gums, perfumes, &c.; xiv. on the grape and the making of wine; xv. on the olive, fig, apple, and other luscious fruits; xvi. on forest trees, canes, and reeds, kinds of timber, and different ages of trees. Book xvii. treats chiefly of the culture of trees, their diseases, and the arts of pruning, manuring, training, &c. Book xviii. is on farming and cereal crops; xix. on other kinds of produce, including horticulture; xx. on the medicinal properties of plants; xxi. on flowers, bees, honey, and on botanical distinctions as to leaves, thorns, and times of flowering. Book xxii. treats of all kinds of herbs used in medicine and in cookery; xxiii. the medicinal properties of cultivated trees; xxiv. the same of forest trees, and their useful products generally. (These two books are chiefly derived from Greek authorities, and include the names and properties of a vast number of species.) Books xxv. to xxvii. inclusive treat of the properties of plants, and these books also are chiefly from Greek sources,—Cornelius Celsus being the principal Roman authority. Books xxviii. to xxx. discuss the medicinal properties residing in animals; xxxi. and xxxii. those in fishes. These books are full of the most extraordinary and nonsensical superstitions, including discussions on magic in book xxx. Book xxxiii. is on the nature and use of the precious metals; xxxiv. on the different kinds of bronze, on lead, iron, and the oxides generally. Book xxxv. is on the origin and practice of painting; xxxvi. on the different kinds of stone and marble, including lime, sand, and gypsum; xxxvii. on precious stones.

It will be observed that, though there is no scientific classification in this long work, a kind of sequence, not altogether unphilosophical, is observed. The amount of matter and the number of subjects treated of in each book are always recorded at the end of the epitome (book i.), just before the list of authors, in the formula, "Summa: res et historiae et observationes mxcvi." &c.; but in the medical books, in place of *res*, "subjects," *medicinae*, "prescriptions," is used. By *historiae* he means "inquiries," or "the results of inquiries," as distinguished from *observationes*, "remarks."

With all its faults, inevitable to the infant state of science, Pliny's work is an astounding monument of industry. It is believed to have been published about two years before his death. He wrote, besides several other treatises,<sup>1</sup> a history of the wars from the first in Germany,<sup>2</sup> in twenty books, and a continuation of the history of Aufidius Bassus down to his own times, in thirty-one books—all now lost.

He is said to have been a great student, an early riser, abstemious and temperate in his meals.<sup>3</sup> In his later days he appears to have grown somewhat unwieldy and asthmatic, for Pliny the younger, in describing his uncle's death by suffocation from the fumes in the eruption of Vesuvius, 79 A.D., says that his breathing "*propter amplitudinem corporis gravior et sonantior erat.*"<sup>4</sup> Pliny's intimate friendship with Vespasian may be inferred from his custom of attending the morning levée; he seems to have first known him in the German wars in the time of Claudius.

Besides his published works, the elder Pliny left, as his nephew tells us, one hundred and sixty note-books of extracts (*electorum commentarios elx.*), written in a very small hand on both sides of the page. So valuable were these volumes considered that Pliny assured his nephew he could have sold them in Spain for £3500, even before the full number had been made up. He acted as procu-

rator in Spain in 71, and was recalled to Rome by the death of his brother-in-law Caius Cæcilius, who by will appointed him guardian of the younger Pliny. At the time of his death, the elder Pliny had the command of the Roman fleet at Misenum. He fell a victim to his imprudent curiosity in advancing within the range of the thickly-falling ashes during the eruption of Vesuvius in 79 A.D.

Pliny's influence on the nomenclature and the popular ideas about common objects long continued to be very extensive, and survived till the dawn of the age of more exact science. The knowledge he gives us of the writings and opinions of so large a number of lost authors opens a view of the whole cycle of the science of the period.

The best editions of the *Natural History* are those by Julius Sillig (Leipsic, 1831-36, in 5 vols. 12mo), and by Louis Janus (Teubner, Leipsic, 1854-59, in 6 vols.), which is virtually a revised reprint of it, the whole of the last volume being occupied with copious and accurate indices of authors and subjects. These may be called critical editions; two French editions with scientific commentaries had preceded,—by Hardouin (1685 and 1723), and by Panckoucke (1829-33), in twenty volumes with a French translation. (F. A. P.)

PLINY THE YOUNGER (61-c. 115 A.D.). Caius Cæcilius Secundus, commonly called Pliny the Younger, was the nephew and heir of the elder Pliny, the naturalist. He was born 61 A.D. at Comum (Como) on the southern shore of Lake Larius in northern Italy, near to which, on the east side, stood the spacious and beautiful family villa.<sup>5</sup> He took the name of Cæcilius from his father, who had married Plinia, the elder Pliny's sister. At ten years of age he was left to the care of Virginius Rufus, a distinguished man and thrice consul.<sup>6</sup>

Pliny was a man of refined taste, highly accomplished, devoted to literature, kind and indulgent to his freedmen and his slaves, gentle and considerate in all his family relations, just in his dealings, munificent in the use of his wealth, humane and forgiving to all who had offended him.<sup>7</sup> By profession an advocate, and a pupil of the famous Quintilian (ii. 14), he was a frequent and very popular pleader at the courts of the centumviri held in the Julian basilica, as well as occasionally in the senate and in public prosecutions (vi. 29).

His fame in centumviral trials, which were chiefly concerned with will cases, is attested by Martial (x. 19, 17), whose epigram he quotes in lamenting the poet's death (iii. 21). But, though himself somewhat ambitious of praise as a pleader (for he seems to have regarded Cicero as his model in everything), he sternly reprobated the arts of bribery and flattery which were commonly adopted by patrons to secure the applause of their clients. "For half-a-crown a head," he complains, "you may fill the benches with any number of shouters and bawlers of your praises." Fond as he was of eloquence, he seems to have given up legal practice from some feeling of disgust at these abuses, and to have devoted himself to the duties of the state-offices. He was appointed augur and præfect of the treasury in the temple of Saturn, and rose in due course through the offices of quæstor, prætor, and tribune of the people, finally attaining to the consulship, 100 A.D. His inaugural address to the emperor Trajan, a long and finished but rather pedantic oration in Ciceronian

<sup>1</sup> Three books, in six volumes, were entitled "*Studiosus*," and eight books bore the title "*Dubius Sermo*." To this last he probably refers, *Præf.* § 28, "*audito—Epicureos quoque parturire adversus libellos quos de grammatica edidi.*"

<sup>2</sup> *Bellorum Germanie viginti (libri), quibus omnia quæ cum Germanis gessimus bella collegit* (Pliny, *Ep.* iii. 5, § 4). A treatise on throwing the lance from horseback, "*De jaculatione equestri*," is mentioned here as his first work, written when he was in command of a squadron of cavalry (*præfectus alæ*).

<sup>3</sup> Pliny, *Ep.* iii. 5, § 16; see *ibid.* §§ 8-10.

<sup>4</sup> *Epist.* vi. 16, § 13.

<sup>5</sup> "*Quid agit Comum, tuæ meæque deliciae?*" he writes to Caninius Rufus, *Ep.* i. 3. He had several country houses on this estate (*plures villæ*, *Ep.* ix. 7). Two of these, his especial favourites, he playfully called "*Tragedy and Comedy*," comparing the low and the lofty site to the *scecus* and the *cothurnus* of the actors.

<sup>6</sup> Pliny speaks of him with great regard in ii. 1, § 8:—"Ille mihi tutor relictus affectum parentis exhibuit."

<sup>7</sup> His motto was "to pardon others as if one daily needed pardon oneself, and to abstain from sins as if one viewed sin as unpardonable," viii. 22. In *Ep.* 2 of the same book he finely says, "*Mihi egregium in primis videtur, ut foris ita domi, ut in magnis ita in parvis ut in alienis ita in suis, agitare justitiam.*"

Latinity, entitled *Panegyricus*, is extant.<sup>1</sup> "The good old custom," he says in his opening sentence, "of commencing all public business with prayers to the gods is especially to be observed by a consul, and on an occasion of offering public thanks to the best of princes by the command of the senate and the state." The piece teaches us a good deal about the imperial policy and the military career of Trajan (§§ 13-16).

Between Pliny and Trajan the sincerest regard and even affection seem to have subsisted. In the last book of the *Epistles*, which contains a hundred and twenty-one letters and replies on matters of business connected with the province between Pliny and the emperor, the latter is always addressed as "Domine" (sire), the former as "Secunde (or mi Secunde) carissime." Most of these were written by Pliny as *propraetor* (103-5) of Bithynia and Pontica, and they show the careful interest taken in the welfare and prosperity of the cities under his charge. The replies of the emperor are characteristically brief; they are written in good and literary Latin, and show Trajan to have been a man of letters as well as a man of business. Pliny's celebrated inquiry what should be done with recusant Christians, in which he says<sup>2</sup> that "not only cities but country towns and rural districts have been touched by the contagion of this superstition," is briefly replied to; "conquirendi non sunt," writes the emperor, "si deferantur et arguantur, puniendi sunt, ita tamen ut qui negaverit se Christianum esse, idque re ipsa manifestum fecerit, id est supplicando dis nostris, quamvis suspectus in praeteritum, veniam ex poenitentia impetret." Pliny had said:—"Those who obstinately persisted that they were Christians, after being warned of the consequence, I ordered to be led off to punishment, not doubting that, whatever it was that they professed, their inflexible obstinacy deserved it." Doubts have even been raised as to the genuineness of a passage which appears so inconsistent with the established Roman policy of tolerating every *superstitio*. But it is clear that what Pliny doubted was the fidelity to the emperor of those who refused to make the customary religious offerings to his statue. It was zeal for loyalty that led him into a course which his humane nature condemned.<sup>3</sup>

Pliny was twice married, but had no children. The emperor bestowed on him the *jus trium liberorum*, which conferred certain state privileges upon those who brought up that number of legitimate children to become Roman citizens. Three affectionate letters, none of them long, are addressed to his second wife Calpurnia Hispana.

In health Pliny seems to have been far from robust. He speaks of his slight and thin figure, "*gracilitas mea*,"<sup>4</sup> though in his youth he had seen military service in the East.<sup>5</sup> He was fond too of hunting, but used to boast that he combined the worship of Diana with that of Minerva.<sup>6</sup>

Pliny's great wealth was most liberally bestowed, both privately and publicly. He undertakes to rebuild a temple of Ceres on his estate, entirely at his own cost, with a

new statue and the addition of a portico, with walls and floor decorated with marbles.<sup>7</sup> To his friend Romatius Firmus, a fellow-townsmen, he writes<sup>8</sup> that in order to have the pleasure of seeing him an *eques* he offers £2500 to make up the equestrian census. To Calpurnia, in addition to nearly £1000 which he had given her as a marriage portion, he offers to remit the whole of the mortgage debt on an encumbered estate which she had inherited from her father. He founded and endowed with landed property an almshouse for people of free birth of both sexes.<sup>9</sup> He presented his nurse with a farm worth nearly £1000;<sup>10</sup> he gave fifty sesteria<sup>11</sup> as a marriage present to the daughter of his tutor Quintilian; he gave up to the township of Comum a sum of about £3500, which, having been illegally left to it by Saturninus, Pliny, as his heir, could have claimed for himself,—and this in addition to over £10,000 which he had already given to the same township. He generously returned a large percentage of the sum he had sold his vintage for, when the produce had been found to disappoint the purchasers.<sup>12</sup> In a beautiful letter to Sabinianus<sup>13</sup> he kindly intercedes for a *libertus* with whom his friend was offended. In a word, the letters are full of acts of Pliny's goodness and generosity, and these are not boastfully expressed, but rather with the view of inciting others by his example.

There are few, if indeed any, remains of Roman prose literature which are as elegant, as interesting, and as varied as Pliny's *Letters*. They were evidently written and published<sup>14</sup> on the model and precedent of Cicero's *Letters*. They are all carefully composed, and couched in the most graceful and polished Latinity. The first letter is a reply to a friend, Septicius, who had often requested Pliny to collect and publish his more carefully written correspondence,—"*si quas paullo curatius scripsisset*." An admirer of nature, and with the faculty for observation perhaps learnt from his uncle, he sometimes describes, and in the most beautiful language, the scenes or wonders he had visited.<sup>15</sup> Of his spacious and beautiful villas in Tuscany and at Laurentum he has given full and detailed accounts, which are of especial value as almost the sole authority on the difficult subject of Roman houses.<sup>16</sup> The Tuscan estate appears to have been his favourite residence. In reply to his friend Fuscus (ix. 38) he gives a pleasing account of the daily life and studies of a refined and temperate man, and a considerate country gentleman, neighbour, and landlord. Of the eruption of Vesuvius in 79 A.D., and the death of his uncle, he gives a minute and evidently faithful account as an eye-witness. This is contained in two long letters<sup>17</sup> to his friend Tacitus the historian. Two excellent ghost-stories are given,<sup>18</sup> and a letter to Tacitus on the omens of dreams<sup>19</sup> shows that both the friends had considerable credulity on this subject.

Like Cicero, but not so frequently, Pliny occasionally<sup>20</sup> "ventilates" his Greek, and he tells us that at the age of fourteen he wrote a Greek tragedy, adding jocosely, "*qualem? inquis: nescio; tragedia vocabatur*" (vii. 4, § 2). Like Cicero too, he was fond of art; he describes with enthusiasm<sup>21</sup> a Corinthian bronze statuette which he had just purchased out of a legacy received.

As a writer Pliny the younger is as graceful, fluent, and polished as the style of the elder Pliny is crabbed and obscure. Indeed, the Latinity of the *epistles* cannot fairly be called inferior to that of Cicero himself. There are few indications of the "deterioration"

<sup>7</sup> ix. 39. A similar offer is made to Trajan, including the dedication of his statue, *Ep. Pl. et Tr.*, 8.

<sup>8</sup> i. 19.

<sup>11</sup> About £430, vi. 32.

<sup>12</sup> ix. 21. "Tunc praecipua mansuetudinis laus," he well says, "cum ira causa iustissima est."

<sup>13</sup> Keil (*Præf.* to ed. Teubner, 1865, p. 1) quotes Sidorius Apollinaris, *Epist.* ix. 1, to show that nine books of his *Letters* were edited by Pliny himself.

<sup>14</sup> *E.g.*, the sources of the Clitumnus, viii. 8, and the floating islands on a lake at Ameria, viii. 20.

<sup>15</sup> See ii. 17 and v. 6. The former describes in glowing terms the Laurentian villa, though he says of it in iv. 6, "*nihil ibi possideo præter tectum et hortum, statimque harenas*"; but he is comparing the extent of other landed properties.

<sup>16</sup> vi. 16 and 20.

<sup>17</sup> i. 18. It is clear from *Ann.* vi. 25 that Tacitus had some belief in astrology. Pliny the elder wrote his history of the German wars "*somnio monitus*," *Ep.* iii. 5, § 4.

<sup>18</sup> *E.g.* in i. 18 and 20; ii. 3; iv. 7; ix. 26.

<sup>19</sup> iii. 6. He says, however (§ 1), that in bronzes he was not much of a critic: "in hac re certa perquam exiguum sapio."

<sup>1</sup> He alludes to it in iii. 13, and in iii. 18 he explains how the address in the senate was afterwards expanded into a book, and recited for three consecutive days to his friends. The title *Panegyricus* appears then to have been given to it.

<sup>2</sup> x. 96, § 9.

<sup>3</sup> The context shows that he had some suspicion that the Christians were forming secret and illegal societies (*heteriæ*, § 8). This is his only excuse for having put two deaconesses (*ministrae*) to the torture, to find out what they really held.

<sup>4</sup> ii. 11, § 15.

<sup>5</sup> iii. 11, § 5.

<sup>6</sup> ix. 20. In i. 6 he gives a droll account of his hunting wild boars, and reading books while the beaters were at work: "*ad retia sedebam; erat in proximo non venabulum aut lancea, sed stilus et pugilares; meditabar aliquid enotabamque, ut si manus vacuas plenas tamen ceras reportarem*."

not unfrequently reaching the Cape Colony, Ceylon, Australia, and even Tasmania. *Charadrius plumicollis* has a much narrower distribution, though where it occurs it is much more numerous as a species. Its breeding quarters do not extend further than from Iceland to western Siberia, but include the more elevated tracts in the British Islands, whence in autumn it spreads itself, often in immense flocks, over the cultivated districts if the fields be sufficiently open. Here some will remain so long as the absence of frost or snow permits, but the majority make for the Mediterranean basin, or the countries beyond, in which to winter; and, as with the Grey Plover, stragglers find their way to the southern extremity of Africa. The same may be said, *mutatis mutandis*, of what are usually deemed to be two other cognate forms, *C. virginicus* and *C. juvencus*, which respectively represent *C. plumicollis* in America and eastern Asia, where they are also known by the same English name. The discrimination of these two birds from one another requires a very acute eye, and room is here wanting in which to specify the minute points in which they differ;<sup>1</sup> but both are easily distinguished from their European ally by their smaller size, their greyish-brown axillary feathers, and their proportionally longer and more slender legs. All, however,—and the same is the case with the Grey Plover,—undergo precisely the same seasonal change of colour, greatly altering their appearance and equally affecting both sexes. In the course of spring or early summer nearly the whole of the lower plumage from the chin to the vent, which during winter has been nearly pure white, becomes dew-black. This is partly due to the growth of new feathers, but partly to some of the old feathers actually changing their colour, though the way in which the alteration is brought about is still uncertain.<sup>2</sup> A corresponding alteration is at the same season observable in the upper plumage; but this seems chiefly due (as in many other birds) to the shading of the lighter-coloured margins of the feathers, and does not produce so complete a transformation of appearance, though the beauty of the wearer is thereby greatly increased.

Though the birds just spoken of are those most emphatically entitled to be called Plovers, the group of Ringed Plovers before mentioned (KILLDEER, vol. xiv. p. 76) and the LEPWINGS (vol. xiv. p. 303), with its allies, have, according to usage, hardly less claim to the name, which is also extended to some other more distant forms that can here have only the briefest notice. Among them one of the most remarkable is the "Zicazac" (so called from its cry)—the *tytochus* of Herodotus (see HUMPHRY-BIRD, vol. xii. p. 355, n. 3), the *Pluvianus* or *Hyas aegyptius* of ornithologists, celebrated for the services it is said to render to the crocodile—a small bird whose plumage of delicate lavender and cream-colour is relieved by markings of black and white. This probably belongs to the small section generally known as Coursers, *Cursarius*, of which some eight or ten species inhabit the deserts of Africa and India, while one, *C. gallicus*, occasionally strays to Europe and even to England. Allied to them are the curious PRATINCOLES (*q.v.*), also peculiar to the Old World, while

the genera *Thimocoris* and *Attagis* form an outlying group peculiar to South America, that is by some systematists regarded as a separate Family *Thimocoridae*, near which are often placed the singular SHEATHBILLS (*q.v.*). By most authorities the Stone-Curlews (*Curlew*, vol. vi. p. 712), the OYSTER-CATCHERS (vol. xviii. p. 111), and TURNSTONES (*q.v.*) are also regarded as belonging to the Family *Charadriidae*, and some would add the Avocets (*Recurvirostra*) and STILTS (*q.v.*), among which the 'Cavalier, *Dromas ardeola*—a form that has been banded about from one Family and even Order to another—should possibly find its resting-place. It frequents the sandy shores of the Indian Ocean and Bay of Bengal from Natal to Aden, and thence to Ceylon, the Malabar coast, and the Andaman and Nicobar Islands,—a white and black bird mounted on long legs, with webbed feet, and a bill so shaped as to have made some of the best ornithologists lodge it among the TERNS (*q.v.*).

Though the various forms here spoken of as Plovers are almost certainly closely allied, they must be regarded as constituting a very indefinite group, for hardly any strong line of demarcation can be drawn between them and the SANDPIPPERS and SNIPES (*q.v.*). United, however, with both of the latter, under the name of *Limicola*, after the method approved by the most recent systematists, the whole form an assemblage the compactness of which no observant ornithologist can hesitate to admit, even if he be not inclined to treat as its nearest relations the Bustards on the one hand and the Gulls on the other, as before suggested (*ORNITHOLOGY*, vol. xviii. p. 45). (A. N.)

PLÜCKER, JULIUS (1801–1868), mathematician and physicist, was born at Elberfeld on the 16th June 1801. After being educated at the gymnasium at Düsseldorf and studying at the universities of Bonn, Heidelberg, and Berlin, he went in 1823 for a short time to Paris, where he came under the influence of the great school of French geometers, whose founder, Monge, was only recently dead; and there can be no doubt that his intercourse with the mathematicians of that school, more particularly with Poncelet and Gergonne, greatly helped to determine the earlier part at least of his career. In 1825 he was received as "privat-docent" at Bonn, and after three years he was made professor extraordinary. The title of his "habilitationsschrift," *Generalem analysen applicationem ad utramque geometriam altioris et mechanice basis et fundamenta sunt e serie Tayloria deducta Julius Plücker* (Bonn, 1824), indicated the course of his future researches. The mathematical influence of Monge had two sides represented respectively by his two great works, the *Geometrie Descriptive* and the *Application de l'Analyse à la Géométrie*. Although fully master of those general ideas of modern geometry whose development began with the publication of the former of these works, Plücker's actual labours lay more in the direction of the latter. It was his aim to furnish modern geometry with suitable analytical methods and thus to give it an independent analytical development. In this effort he was as successful as were his great contemporaries Poncelet and Steiner in cultivating geometry in its purely synthetical form. From his lectures and researches at Bonn sprang his first great work *Analytisch-Geometrische Entwicklungen* (vol. i. 1828, vol. ii. 1831).

In the first volume of this treatise Plücker introduced for the first time<sup>3</sup> the method of abridged notation which has become one of the characteristic features of modern analytical geometry. The peculiarity of this method consists in this, that the letters used in the equations of curves and surfaces represent, not coordinates of a point with respect to arbitrary chosen axes, but straight lines, or it may be curves or surfaces, intrinsically related to the figure

<sup>1</sup> Seefelt (*Mus. Pigeon-Birds, Curlew*, p. 53) states that in some examples it seems impossible to determine the form to which they belong; but ordinarily American specimens are rather larger and rounder, and have shorter toes than those from Asia.

<sup>2</sup> It is much to be regretted that ornithologists favourably situated in regard to zoological gardens have not more extensively used opportunities which might then be accorded to them of conducting useful observations on this subject and others of similar kind. Elsewhere it would be hardly possible to carry on such an investigation, and even under the best circumstances it would not be easy and would require unremitting attention. The results of some partial observations superintended by Furell in the gardens of the Zoological Society of London are given in his *Transactions* (i. pt. 12–13). Little has been done there since of this nature.

<sup>3</sup> The independent development of a similar idea by the brilliant young French geometer Boëlle (1797–1832) was cut short by his premature death.

under discussion. For example, if it be wished to investigate the properties of a conic section with respect to a pair of tangents and their chord of contact, we write its equation  $uv + w^2 = 0$ , where  $u=0$ ,  $v=0$ ,  $w=0$  represent the two tangents and the chord of contact respectively. This procedure has two great advantages. It enables us to greatly abridge the necessary analytical equations, to arrive at them more easily, and thus to lighten or altogether avoid the cumbersome algebraical calculations which had broken the back of the old-fashioned Cartesian progress altogether; and it greatly

interpretation of analytical results which had hitherto been obscure. In the first volume of the *Entwickelungen*, Plücker applied the method of abridged notation to the straight line, circle, and conic sections, and he subsequently used it with great effect in many of his researches, notably in his theory of cubic curves.

In the second volume of the *Entwickelungen*, Plücker clearly established on a firm and independent basis the great principle of duality. This principle had originally been established by Poncelet as a corollary on the theory of the pole and polar of a conic section. Gergonne maintained the independent and fundamental nature of the principle, and hence arose a violent discussion between him and Poncelet into which Plücker was drawn. He settled the matter in Gergonne's favour by introducing the notion of the coordinates of a line and of a plane, and showing that in plane geometry, for example, we could with equal readiness represent a point either by means of coordinates or by means of an equation, and that the same was true of a line. Hence it appeared that the point or the line in plane geometry, and the point or the plane in solid geometry, could with equal readiness and with equal reason be taken as elements. It was thus made evident that any system of equations proving a theorem regarding points and lines or regarding points and planes could at once be read as proving another in which the words *point* and *line* or the words *point* and *plane* were everywhere interchanged.

Another subject of importance which Plücker took up in the *Entwickelungen* was the curious paradox noticed by Euler and Cramer, that, when a certain number of the intersections of two algebraical curves are given, the rest are thereby determined. Gergonne had shown that when a number of the intersections of two curves of the  $(p+q)$ th degree lie on a curve of the  $p$ th degree the rest lie on a curve of the  $q$ th degree. Plücker finally (*Gergonne Ann.*, 1823-29) showed how many points must be taken on a curve of any degree so that curves of the same degree (infinite in number) may be drawn through them, and proved that all the points, beyond the given ones, in which these curves intersect the given one are fixed by the original choice. Later, simultaneously with Jacobi, he extended these results to curves and surfaces of unequal order. Allied to the matter just mentioned was Plücker's discovery of the six equations connecting the numbers of singularities in algebraical curves. It will be best described in the words of Clebsch:—"Cramer was the first to give a more exact discussion of the singularities of algebraical curves. The consideration of singularities in the modern geometrical sense originated with Poncelet. He showed that the class  $k$  of a curve of the  $n$ th order, which Gergonne by an extraordinary mistake had considered to be identical with its order, is in general  $n(n-1)$ ; and hence arose a paradox whose explanation became possible only through the theory of the simple singularities. By the principle of duality the order  $n$  of a curve should be derived in the same way from the class  $k$  as  $k$  is from  $n$ . But if we derive  $n$  in this way from  $k$  we return not to  $n$  but to a much greater number. Hence there must be causes which effect a reduction during this operation. Poncelet had already recognized that a double point reduces the class by 2, a cusp at least by 3, and a multiple point of the  $p$ th order, all of whose tangents are distinct, by  $\frac{1}{2}p(p-1)$ . Here it was that Plücker took up the question. By first directly determining the number of the points of inflexion, considering the influence of double points and cusps, and finally applying the principle of duality to the result obtained, he was led to the famous formulæ for the singularities of curves which bear his name, and which completely resolve the paradox of Poncelet—formulæ which already in the year 1854 Steiner could cite as the 'well known,' without, however, in any way mentioning Plücker's name in connexion with them. Plücker communicated his formulæ in the first place to *Crelle's Journal*, vol. xii. (1831), and gave a further extension and complete account of his theory in his *Theorie der Algebraischen Curven*, 1839."

In 1833 Plücker left Bonn for Berlin, where he occupied for a short time a post in the Friedrich Wilhelm's Gymnasium. He was then called in 1834 as ordinary professor of mathematics to Halle. While there he published his *System der Analytischen Geometrie, auf neue Betrachtungsweisen gegründet, und insbesondere eine Ausführliche Theorie der Curven dritter Ordnung enthaltend*, Berlin, 1835. In this work he introduced the use of linear functions in place of the ordinary coordinates, and thereby increased the generality

and elegance of his equations; he also made the fullest use of the principles of collineation and reciprocity. In fact he develops and applies to plane curves, mainly of the third degree, the methods which he had indicated in the *Entwickelungen* and in various memoirs published in the interim. His discussion of curves of the third order turned mainly on the nature of their asymptotes, and depended on the fact that the equation to every such curve can be put into the form  $pqr + \mu s = 0$ . He gives a complete enumeration of them, including two hundred and nineteen species. In 1836 Plücker returned to Bonn as ordinary professor of mathematics. Here he published his *Theorie der Algebraischen Curven* which formed a continuation of the *System der Analytischen Geometrie*. The work falls into two parts, which treat of the asymptotes and singularities of algebraical curves respectively; and extensive use is made of the method of counting constants which plays so large a part in modern geometrical researches. Among the results given we may mention the enumeration of curves of the fourth order according to the nature of their asymptotes, and according to the nature of their singularities, and the determination for the first time of the number of double tangents of a curve of the fourth order devoid of singular points.

From this time Plücker's geometrical researches practically ceased, only to be resumed towards the end of his life. It is true that he published in 1846 his *System der Geometrie des Raumes in neuer Analytischer Behandlungsweise*, but this contains merely a more systematic and polished rendering of his earlier results. It has been said that this cessation from pure mathematical work was due to the inappreciative reception accorded by his countrymen to his labours, and to their jealousy of his fame in other lands; it seems likely, however, that it was due in some degree to the fact that he was called upon to undertake the work of the physical chair at Bonn in addition to his proper duties. In 1847 he was made actual professor of physics, and from that time his wondrous scientific activity took a new and astonishing turn.

Plücker now devoted himself to experimental physics in the strictest sense as exclusively as he had formerly done to pure mathematics, and with equally brilliant results. His first physical memoir, published in *Poggendorff's Annalen*, vol. lxxii., 1847, contains his great discovery of magnecrystalline action. Then followed a long series of researches, mostly published in the same journal, on the properties of magnetic and diamagnetic bodies, establishing results which are now part and parcel of our magnetic knowledge. It is unnecessary here to analyse these researches, of which an account has been given in the article *MAGNETISM* (vol. xv. p. 262 sq.); it will be sufficient to say that in this work Plücker was the worthy collaborateur, and, had it not been that their fast friendship and mutual admiration renders the word inappropriate, we might have said rival, of Faraday.

In 1858 (*Pogg. Ann.*, vol. ciii.) he published the first of his classical researches on the action of the magnet on the electric discharge in rarefied gases (see *ELECTRICITY*, vol. viii. p. 74). It is needless now to dilate upon the great beauty and importance of these researches, which remain the leading lights in one of the darkest channels of magnetic science. All the best work that has recently been done on this important subject is simply development of what Plücker did, and in some instances (notably in many of the researches of Crookes) merely reproduction on a larger scale of his results.

Plücker, first by himself and afterwards in conjunction with Hittorf, made many important discoveries in the spectroscopy of gases. He was the first to use the vacuum tube with the capillary part now called a Geissler's tube,

by means of which the luminous intensity of feeble electric discharges was raised sufficiently to allow of spectroscopic investigation. He anticipated Bunsen and Kirchhoff in announcing that the lines of the spectrum were characteristic of the chemical substance which emitted them, and in indicating the value of this discovery in chemical analysis. According to Hittorf he was the first who saw the three lines of the hydrogen spectrum, which a few months after his death were recognized in the spectrum of the solar protuberances, and thus solved one of the mysteries of modern astronomy. For a fuller account of the important discoveries regarding the influence of temperature and pressure on the nature of gaseous spectra made in conjunction with Hittorf see SPECTRUM ANALYSIS.

Hittorf, who had good means of knowing, tells us that Plücker never attained great manual dexterity as an experimenter. He had always, however, very clear conceptions as to what was wanted, and possessed in a high degree the power of putting others in possession of his ideas and rendering them enthusiastic in carrying them into practice. Thus he was able to procure from the Sayner Hütte in 1846 the great electromagnet which he turned to such noble use in his magnetic researches; thus he attached to his service his former pupil the skilful mechanic Fessel; and thus he discovered and fully availed himself of the ability of the great glass-blower Geissler, in conjunction with whom he devised many of those physical instruments whose use all over the civilized world has rendered the name of the artificer of Bonn immortal. It was thus also that, when he felt his own want of chemical knowledge and manipulative skill, he sought and obtained the assistance of Hittorf, one of the ablest of German experimenters.

Induced by the encouragement of his mathematical friends in England, Plücker in 1865 returned once more to the field in which he first became known to fame, and adorned it by one more great achievement—the invention of what is now called Line Geometry. A remark containing the fundamentally new idea of this new geometry had, as Clebsch remarks, already been embodied in the *System der Geometrie des Raumes*:—"A straight line depends on four linear constants. The four magnitudes which we consider as variables receive for any given line constant values, which may be easily constructed and are the four coordinates of the straight line. A single equation between these four coordinates does not determine a locus for the straight line, but merely a law according to which infinite space is made up of straight lines." Here we have the new idea of the straight line considered as an element of space, and of the "complex," as Plücker afterwards called it, made up of a threefold infinity of straight lines subject to a onefold relation. Space thus becomes as it were four-dimensioned, and we have, instead of the three degrees of freedom of space considered as an aggregate of points, four degrees of freedom according as the linear element is (1) absolutely unconditioned, (2) subject to a onefold, (3) subject to a twofold, or (4) subject to a threefold relation. In the first case we have the complex of straight lines, in the second the congruency of lines, in the third the regulus or ruled surface. The last of these geometrical figures had been considered long before, and even the congruency had been discussed before or independently of Plücker, notably by Hamilton and Kummer. The general conception of the linear complex seems to be entirely due to Plücker. At all events he developed the notion to such an extent that he is entitled to be called the founder of Line Geometry, in which the theory of the complex holds a super-fundamental position. His first memoir on the subject was published in the *Philosophical Transactions* of the London Society of London. It attracted much attention,

and almost at once became the source of a large literature in which the new science was developed. Plücker himself worked out the theory of complexes of the first and second order, introducing in his investigation of the latter the famous complex surfaces of which he caused those models to be constructed which are now so well known to the student of the higher mathematics. He was engaged in bringing out a large work embodying the results of his researches in Line Geometry when he died on the 22d May 1868. The work was so far advanced that his pupil and assistant Klein was able to complete and publish it, thereby erecting the worthiest monument to the genius of his master, whose wonderful scientific activity endured to the very last. Of the very numerous honours bestowed on Plücker by the various scientific societies of Europe it may suffice to mention here the Copley medal, awarded to him by the Royal Society two years before his death.

Most of the facts in the above notice have been taken from Clebsch's obituary notice of Plücker (*Abh. d. Kön. Ges. d. Wiss. z. Göttingen*, xvi., 1871), to which is appended an appreciation of Plücker's physical researches by Hittorf, and a list of Plücker's works by F. Klein. See also Gerhardt, *Geschichte der Mathematik in Deutschland*, p. 262; and Plücker's life by Dronke (*G. OH.*) (Bonn, 1871).

PLUM (*Prunus*). Our cultivated plums are supposed to have originated from one or other of the species *P. domestica* or *P. insititia*. The young shoots of *P. domestica* are glabrous, and the fruit oblong; in *P. insititia* the young shoots are pubescent, and the fruit more or less globose. A third species, the common sloe or blackthorn, *P. spinosa*, has stout spines; its flowers expand before the leaves; and its fruit is very rough to the taste, in which particulars it differs from the two preceding. These distinctions, however, are not maintained with much constancy. *P. domestica* is a native of Anatolia and the Caucasus, and is considered to be only naturalized in Europe. *P. insititia*, on the other hand, is wild in southern Europe, in Armenia, and along the shores of the Caspian. In the Swiss lake-dwellings stones of the *P. insititia* as well as of *P. spinosa* have been found, but not those of *P. domestica*. Nevertheless, the Romans cultivated large numbers of plums. The cultivated forms are now extremely numerous, some of the groups, such as the green gages, the damsons, and the egg plums being very distinct, and even reproducing themselves from seed. This, however, cannot be depended on, and hence the choice varieties are propagated by budding or by layers. The colour of the fruit varies from green, pale yellow, red, up to deep purple, the size from that of a small cherry to that of a walnut; the form is oblong acute or obtuse at both ends or globular; the stones or kernels vary in like manner; and the flavour, season of ripening, and duration are all subject to variation. From its hardihood the plum is one of the most valuable fruit trees for the farmer, as it is not particular as to soil, and the crop is less likely to be destroyed by spring frosts. Prunes and French plums are merely plums dried in the sun. Their preparation is carried on on a large scale in Bosnia and Servia, as well as in Spain, Portugal, and southern France. The cherry plum, *Prunus myrobalana*, is employed chiefly as a stock for grafting upon, and for the sake of its ornamental flowers. See also HORTICULTURE, vol. xii. p. 275.

PLUMBAGO, a name frequently applied to graphite in allusion to its remote resemblance to lead, whence it is popularly called "black lead." When Scheele, in 1779, examined this mineral he regarded it as a compound of carbon and iron, and consequently termed it a "carburet of iron"; but Vanuxem in 1825 showed that the iron existed in the form of an oxide, and was not essential to the constitution of the mineral—a conclusion also reached about this time by Karsten. It thus became fully estab-

lished that plumbago is simply an impure form of native carbon. Plumbago is principally used in the manufacture of "black-lead" pencils, for which purpose it was at one time very extensively worked at Borrowdale in Cumberland. It was known locally as "wad," and a grant of the manor of Borrowdale, as far back as the reign of James I., refers to "the wad-holes and wad, commonly called black cawke." The Cumberland plumbago is found in pipes, strings, and irregular masses known as "sops," which occur in a dyke of diorite, associated with a compact blue diabase, penetrating some of the altered ash-beds of the volcanic series. Important mines of plumbago, yielding fine pencil-lead, were opened some years ago by M. Alibert in the government of Irkutsk in eastern Siberia. A good deal of plumbago is also worked near Passau in Bavaria. The graphite so largely used, when mixed with fire-clay, in the manufacture of "black-lead" crucibles, is obtained chiefly from Ceylon; and it is notable that, notwithstanding the purity of the Ceylon plumbago, it is not applicable to the manufacture of lead pencils. Large quantities of plumbago occur in the Laurentian limestones of Canada; while in the United States the mineral is worked at Sturbridge, Mass.; at Ticonderoga and Fishkill, N.Y.; at Brandon, Vt.; and at Wake, N.C. It was formerly yielded by the mines of Ashford in Connecticut. Among the minor applications of plumbago may be mentioned its use as a lubricating agent for machinery and for polishing cast iron. In the preamble to an Act for protecting the black-lead mines of Cumberland, 25 Geo. II. c. 10, it is stated that plumbago is necessary "for divers useful purposes, and more particularly in the casting of bomb-shells, round shot, and cannon balls." It was formerly held in repute in medicine, and a writer on the Cumberland plumbago in 1769 asserts—"It's a present remedy for the cholick; it cures the pain of gravel stone and strangury; and for these and the like uses it's much bought up by apothecaries and physicians." It is notable that plumbago is occasionally found in masses of meteoric iron, and that a substance of similar physical and chemical characters is produced in the blast-furnace during the preparation of cast iron, and is known to the workmen as *livh*. Plumbago bears a strong resemblance to the mineral termed molybdenite, while it resembles to a less extent certain varieties of micaceous iron-ore; the molybdenite, however, is easily distinguished by giving a slightly greenish streak, while the iron-ore yields a red streak.

For the mineralogical characteristics of plumbago or graphite, see vol. xvi. p. 331; for its chemical relations, vol. vi. p. 55; and for its use in crucible-making, vol. ix. p. 543.

**PLUNKET, WILLIAM CONINGHAM PLUNKET, BARON** (1765–1854), an eminent lawyer, orator, and statesman, was born in the county of Fermanagh in July 1765. He was educated in boyhood by his father, a man of considerable ability and reputation; and in 1779 he became a student of Trinity College, Dublin. Though well versed in regular academic studies, he was most conspicuous in his university career as the acknowledged leader of the Historical Society, the debating club of Trinity College, then full of young men of remarkable promise.

Having entered Lincoln's Inn in 1784, Plunket was called to the Irish bar in 1787. His intellect was exactly that of a jurist or a great master of equity—not too refining or overprone to speculation, and yet capable of the highest legal generalizations, and of applying them to masses of fact, however tedious and complicated. His power of close and rapid argument was very remarkable, his memory equally capacious and exact, and he had enriched an ample store of professional learning with the fruits of assiduous general study. Although at first his progress at the bar was not rapid, he gradually obtained

a considerable practice in equity; and, after an apprenticeship of eleven years as a junior, he was raised to the rank of king's counsel in 1798.

In 1795 he entered the Irish parliament as member for Charlemont. His political faith was already settled, and was only slightly modified in after life, at least as regards its cardinal tenets. He was an anti-Jacobin Whig of the school of Burke, not ungracefully filled with a fervent Irish patriotism. He disliked the principles of the French Revolution, and its excesses made such an impression upon him that he always showed the greatest antipathy to merely democratic movements. But he was a sincere admirer of the constitutional government of England as established in 1688; he even justified the ascendancy it had given to the Established Church, although he thought that the time had arrived for extending toleration to Roman Catholics and dissenters. To transfer it to Ireland as thus modified, and under an independent legislature, was even in his youth the only reform he sought for his country; and, although he opposed the Union with all his power, this was only because he thought it incompatible with this object.

When Plunket became a member of parliament, the Irish Whig party was almost extinct, and Pitt was feeling his way to accomplish the Union. In this he was seconded ably by Lord Castlereagh, by the panic caused by a wild insurrection, and by the secession of Grattan from politics. When, however, the measure was actually brought forward, it encountered a vehement opposition; and among the ablest and fiercest of its adversaries was Plunket, whose powers as a great orator were now universally recognized. His speeches in these debates show all the force of reasoning, the admirable arrangement, and the grasp of facts which characterize his later efforts; but they are somewhat disfigured by personal invective, and here and there betray an indecent acrimony. They raised him, however, immediately to the front rank of his party; and, when Grattan re-entered the moribund senate, he took his seat next to Plunket, thus significantly recognizing the place the latter had attained.

After the union of Great Britain and Ireland Plunket returned to the practice of his profession, and became at once a leader of the equity bar. In 1803, after the outbreak of Emmet's rebellion, he was selected as one of the crown lawyers to prosecute the unfortunate enthusiast, and at the trial, in summing up the evidence, delivered a speech of remarkable power, which shows his characteristic dislike of revolutionary outbursts. For this speech he was exposed to much unmerited obloquy, and more especially to the abuse of Cobbett, against whom he brought a successful action for damages. In 1804, in Pitt's second administration, he became solicitor-general and then attorney-general for Ireland; and he continued in office when Lord Grenville came into power at the head of the ministry of All the Talents. Plunket held a seat in the imperial parliament during this period, and there made several able speeches in favour of Catholic emancipation, and of continuing the war with France; but, when the Grenville cabinet was dissolved, he returned once more to professional life, and for some years devoted himself exclusively to it.

In 1812, having amassed a considerable fortune, he re-entered parliament as member for Trinity College, and identified himself thoroughly with the Grenville or anti-Gallican Whigs. He was now in the full maturity of his powers, and very soon was acknowledged one of the first orators, if not the first, of the House of Commons. His reverence for the English constitution in church and state, his strong dislike of French principles, his steady advocacy of the war with Napoleon, and his antipathy to anything like democracy made him popular with the Tory party. On the other hand, he was the zealous and most able exp-

porter of Catholic emancipation; he was not averse to some measure of parliamentary reform; and, as generally he was on the side of constitutional progress, he was reckoned a principal ornament of one of the sections of the Whigs.

In 1822 Plunket was once more attorney-general for Ireland, with Lord Wellesley as lord-lieutenant. One of his first official acts was to prosecute for the "bottle riot," an attempt on his part to put down the Orange faction in Ireland. But, though always the advocate of the Catholic claims, he strenuously opposed the Catholic Association, which about this time, under the guidance of O'Connell, began its extraordinary and successful agitation. He struggled vehemently to extinguish it, and in 1825 made a powerful speech against it; and thus the curious spectacle was seen of the ablest champion of an oppressed sect doing all in his power to check its efforts to emancipate itself.

In 1827 Plunket was made master of the rolls in England; but, owing to the professional jealousy of the bar, who not unnaturally thought him an intruder, he was obliged to abandon this office. Soon afterwards he became chief justice of the common pleas in Ireland, and was then created a peer of the United Kingdom. In 1830 he was appointed lord chancellor of Ireland, and held the office, with an interval of a few months only, until 1841, when he finally retired from public life. During this period he made some able speeches in favour of parliamentary reform; but they were scarcely equal to his earlier efforts; and his reputation as a judge, though far from low, was not so eminent as might have been expected. He died in 1854, in his ninetyeth year. (W. O. M.)

PLUSH (French *Peluche*), a textile fabric having a cut nap or pile the same as fustian or velvet. Originally the pile of plush consisted of mohair or worsted yarn, but now silk by itself or with a cotton backing is used for plush, the distinction from velvet being found in the longer and less dense pile of plush. The material is largely used for upholstery and furniture purposes, and is also much employed in dress and millinery. The most distinctive form of plush is that which has taken the place of the napped beaver felt in the dress hats of gentlemen, which are now consequently known as "silk" hats. That plush, a considerable manufacture, is principally made in Lyons.

PLUTARCH (Πλούταρχος Χαιρωνεύς), a Greek prose writer, born at Chæronea in Bœotia, and a contemporary of Tacitus and the Plinys. The precise dates of his birth and death are unknown; but it is certain that he flourished under the Roman emperors from Nero to Trajan inclusive, so that from 50 to 100 A.D. will probably include the best years of his life. There is some probability that he outlived Trajan,<sup>1</sup> who died in 117. In the *Consolation to his Wife* on the loss of his young daughter, he tells us (§ 2) that they had brought up four sons besides, one of whom was called by the name of Plutarch's brother, Lamprias. We learn incidentally from this treatise (§ 10) that the writer had been initiated in the secret mysteries of Dionysus, which held that the soul was imperishable. He seems to have been an independent thinker rather than an adherent to any particular school of philosophy. His forte, so to say, was learning, and the application of it to the casualties of human existence. His vast acquaintance with the literature of his time is everywhere apparent; and with history especially he was thoroughly conversant, and hardly less so with physics.

The celebrity of Plutarch, or at least his popularity, is mainly founded on his forty-six *Parallel Lives*. He is thought to have written this work in his later years after

<sup>1</sup> The scanty evidences of date collected from Plutarch's writings are well discussed by Long in Smith's *Lit. of Biog.*, iii. p. 429.

his return to his native town Chæronea. His knowledge of Latin and of Roman history he must have partly derived from some years' residence in Rome and other parts of Italy,<sup>2</sup> though he says he was too much engaged in lecturing (doubtless in Greek, on philosophy) to turn his attention much to Roman literature during that period. Long observes that "we must expect to find him imperfectly informed on Roman institutions, and we can detect in him some errors. Yet, on the whole, his Roman lives do not often convey erroneous notions; if the detail is incorrect, the general impression is true."

Plutarch's design in writing the *Parallel Lives*—for this is the title which he gives them in dedicating *Theseus* and *Romulus* to Sosius Senecio—appears to have been the publication, in successive books, of authentic biographies in pairs, a Greek and a Roman (generally with some approximation to synchronism as well as some well-marked resemblances in political career) being selected as the subject of each. In the introduction to the *Theseus* he speaks of having already issued his *Lycurgus* and *Numa*, viewing them, no doubt, as bearing a resemblance to each other in their legislative character; and so *Theseus* and *Romulus* are compared as the legendary founders of states.

In the opening sentence of the life of Alexander he says that "in this book he has written the lives of Alexander and Cæsar" (Julius), and in his *Demosthenes*, where he again (§ 1) mentions his friend Sosius, Σόσιος, he calls the life of this orator and Cicero the fifth book.<sup>3</sup> It may therefore fairly be inferred that Plutarch's original idea was simply to set (παράβαλλεν, *Nic.*, § 1) a Greek warrior, statesman, orator, or legislator side by side with some noted Roman celebrated for the same qualities. In his age, when Rome held the supremacy, but Greece was still looked up to as the centre and source of wisdom and art, such a comparison of the greatest men of both nations had a special propriety and significance, and was more than a mere literary exercise. It was a patriotic theme, to show the superiority of this or that race; and Plutarch, in a sense, belonged to both. Now Alexander and C. Cæsar, Demosthenes and Cicero, Solon and Valerius Publicola, have some fairly obvious resemblances, which are not so conspicuous in some other pairs. But the sequel which follows most (not all) of the *Lives*, entitled σύγκρισις, viz., a comparison in detail, is by modern critics rejected as spurious. It was manifestly added as an appendix from a misapprehension of Plutarch's real motive; the effort to bring out exact points of resemblances which are either forced or fanciful far exceeded the design contemplated by him. Moreover, the marked difference in style between the βίαι and the σύγκρισις is quite decisive of the question.

Nearly all the lives are in pairs; but the series concludes with single biographies of Artaxerxes, Aratus (of Sicyon), Galba, and Otho. In the life of Aratus, not Sosius Senecio, but one Polycrates, is addressed.

It is not to be supposed that Plutarch was content to write merely amusing or popular biographies. On the contrary, the *Lives* are works of great learning and research, and they must for this very reason, as well as from their considerable length, have taken many years in their compilation. For example, in the life of Theseus the following long list of authorities appears:—the Megarian historians,<sup>4</sup> Hellanicus, Simonides, Philochorus, Pherecydes, Demo, Pæon of Amathus, Dicaearchus, Hero-

<sup>2</sup> *Demosth.*, § 2. Plutarch's orthography of Roman words and names is important as bearing on the question of pronunciation. A curious example (*De Fortun. Rom.*, § 5) is *Virtutis et Honoris*, written Οὐιτρούρις τε καὶ Οὐᾶρις. The Volsci are Οὐολούσκοι, *ibid.*

<sup>3</sup> It is quite evident that the original order of the books has been altered in the series of *Lives* as we now have them.

<sup>4</sup> Οἱ Μεγαροὶ συγγραφεῖς, referred to in § 10.

dorus, Bio, Menecrates, Clidemus, Hereas, Ister,<sup>1</sup> Diodorus. For the life of Romulus he refers to "one Promathio who composed a history of Italy" (§ 2 fin.), Diocles of Peparethus, Fabius Pictor, Herodorus, Varro, Valerius, Juba (Ἰόβας), Zenodotus of Træzen, Simulus the poet (from whom he quotes eight elegiac verses), Antigonus, "one Butas,"<sup>2</sup> and Caius Acilius, and (as a *vivæ vocis* informant) Sextius Sulla of Carthage. In the life of Lycurgus he cites Aristotle, Eratosthenes, Apollodorus, Timæus, Xenophon, Simonides, Aristocrates the Spartan, Sphaerus, Critias, Theophrastus, Diocorides, Hippias the sophist, Philostephanus, Demetrius Phalereus, Hermippus, Sosibius, Thucydides, Apollonius, Aristoxenus, Aristocrates. In the life of Alexander, which is a long and elaborate essay, mention is made of Onesicritus, Aristobulus, Duris, Charcas, Callisthenes, Eratosthenes, Clitarchus, Polyclitus, Antigeneis, Ister, Ptolemæus, Anticlides, Philo of Thebes, Philippus of Theangele, Philippus of Eretria, Hecateus, Hermippus, Sotion.

It is true that many of the lives, especially of Romans, do not show such an extent of research or such a wealth of authorities. But Plutarch must have possessed or had access to a great store of books, and his diligence as an historian cannot be questioned, if his accuracy is in some points impeached.

His sympathy with Doric characters and institutions is very evident; he delights to record the exploits, the maxims, and the virtues of Spartan kings and generals. This feeling is the key to his apparently unfair and virulent attack on Herodorus, who, as an Ionian, seemed to him to have exaggerated the prowess and the foresight of the Athenian leaders.

The voluminous and varied writings of Plutarch exclusive of the *Lives* are known under the common term *Opera Moralia*. These consist of above sixty essays, some of them long and many of them rather difficult, some too of very doubtful genuineness. Their literary value is greatly enhanced by the large number of citations from lost Greek poems, especially verses of the dramatists, among whom Euripides holds by far the first place. They evince a mind of vast and varied resources, historical as well as philosophical—the mind of an inquirer and a seeker after knowledge, rather than that of an exponent or an opponent of any particular philo-sophical system.

But Plutarch's Greek is not, like Lucian's, fluent and easy, nor even clear. He uses many words not in the ordinary Greek vocabulary, and he too often constructs long sentences, the thread of which separately, as well as the connexion, cannot be traced without close attention. Hence he is unattractive as a writer, so far as style is concerned, and he is often diffuse and carries his discussions to an unnecessary length.

It is certain that to most persons in Britain, even to those who call themselves scholars, the *Opera Moralia* of Plutarch are practically almost unknown. No English translation of them, we believe, has been printed since the bulky folio of Philemon Holland, published at the end of the 17th century, with the exception of a single volume in Bohn's Classical Library, lately added to that series by Mr C. W. King, M.A. It is therefore the more desirable to devote the remainder of this article to a brief notice of the principal treatises.

*On the Education of Children* recommends (1) good birth, and sobriety in the father; (2) good disposition and good training are alike necessary for virtue; (3) a mother ought to nurse her own offspring, on the analogy of all animals; (4) the *paidagogus* must be honest and trustworthy; (5) all the advantages of life and fortune must be held secondary to education; (6) mere mob-oratory is no

part of a good education; (7) philosophy should form the principal study, but not to the exclusion of the other sciences; (8) gymnastics are to be practised; (9) kindness and advice are better than blows; (10) over-pressure in learning is to be avoided, and plenty of relaxation is to be allowed; (11) self-control, and not least over the tongue, is to be learned; (12) the grown-up youth should be under the eye and advice of his father, and all bad company avoided, flatterers included; (13) fathers should not be too harsh and exacting, but remember that they were themselves once young; (14) marriage is recommended, and without disparity of rank; (15) above all, a father should be an example of virtue to a son.

*How a Young Man ought to Hear Poetry* is largely made up of quotations from Homer and the tragic poets. The points of the essay are the moral effects of poetry as combining the true with the false, the praises of virtue and heroism with a mythology depraved and unworthy of gods, *εἰ θεοὶ τι δρῶσι φαῦλον, οὐκ εἰσὶν θεοὶ* (§ 21). "So long as the young man," says Plutarch, "admires what is rightly said and done in the poets, but feels annoyed at the contrary, no harm is done; but if he learns to admire everything which is presented to him under the name of a hero, he will unconsciously become morally deteriorated" (§ 26).

*On the Right Way of Hearing* (*περὶ τοῦ ἀκοῦειν*) advocates the listening in silence to what is being said, and not giving a precipitate reply to statements which may yet receive some addition or modification from the speaker (§ 4). The hearer is warned not to give too much weight to the style, manner, or tone of the speaker (§ 7), not to be either too apathetic or too prone to praise, not to be impatient if he finds his faults reproved by the lecturer (§ 16). He concludes with the maxim, "to hear rightly is the beginning of living rightly," and perhaps he has in view throughout his own profession as a lecturer.

*How a Flatterer may be Distinguished from a Friend* is a rather long and uninteresting treatise. The ancient writers are full of warnings against flatterers, who do not seem to exercise much influence in modern society. The really dangerous flatterer (§ 4) is not the parasite, but the pretender to a disinterested friendship,—one who affects similar tastes, and so insinuates himself into your confidence. Your accomplished flatterer does not always praise, but flatters by act, as when he occupies a good seat at a public meeting for the express purpose of resigning it to his patron (§ 15). A true friend, on the contrary, speaks freely on proper occasions. A good part of the essay turns on *παρηγορία*, the honest expression of opinion. The citations, which are fairly numerous, are mostly from Homer.

*How one may be Conscious of Progress in Goodness* is addressed to Sosius Seneccio, who was consul in the last years of Nerva, and more than once (99, 102, 107) under Trajan. If, says Plutarch, a man could become suddenly wise instead of foolish, he could not be ignorant of the change; but it is otherwise with moral or mental processes. Gradual advance in virtue is like steady sailing over a wide sea, and can only be measured by the time taken and the forces applied (§ 3). Zeno tested advance by dreams (§ 12); if no excess or immorality presented itself to the imagination of the sleeper, his mind had been purged by reason and philosophy. When we love the truly good, and adapt ourselves to their looks and manners, and this even with the loss of worldly prosperity, then we are really getting on in goodness ourselves (§ 15). Lastly, the avoidance of little sins is an evidence of a scrupulous conscience (§ 17).

*How to get Benefit out of Enemies* argues that, as primitive man had savage animals to fight against, but learnt to make use of their skins for clothing and their flesh for food, so we are bound to turn even our enemies to some good purpose. One service they do to us is to make us live warily against plots; another is, they induce us to live honestly, so as to vex our rivals not by scolding them but by making them secretly jealous of us (§ 4). Again, finding fault leads us to consider if we are ourselves faultless, and to be found fault with by a foe is likely to be plain truth speaking, *ἀκουστέον ἔστι παρὰ τῶν ἐχθρῶν τὴν ἀλήθειαν* (§ 6). Jealousies and strifes, so natural to man, are diverted from our friends by being legitimately expended on our enemies (§ 10).

*On Having Many Friends, On Chance, On Virtue and Vice*, are three short essays, the first advocating the concentration of one's affections on a few who are worthy (*τοὺς ἀξιῶν φίλους διώκειν*, § 4), rather than diluting them, as it were, on the many; the second pleads that intelligence, *φρόνησις*, not mere luck, is the ruling principle of all success; the third shows that virtue and vice are but other names for happiness and misery. All these are interspersed with citations from the poets, several of them unknown from other sources.

A longer treatise, well and clearly written, and not less valuable for its many quotations, is the *Consolation addressed to Apollonius*, on the early death of his "generally beloved and religious and dutiful son." Equality of mind both in prosperity and in adversity is recommended (§ 4), since there are "ups and downs" (*εὐχὰς καὶ ταπεινότης*) in life, as there are storms and calms on the sea, and good and bad seasons on the earth. That man is born to reverse

<sup>1</sup> Ὁ Ἰστρος ἐν τῇ τρισκαίδεκάτῃ τῶν Ἀττικῶν, § 31.

<sup>2</sup> Βούτας τις αἰτίας αὐθάδεις ἐν ἐλεγείοις περὶ τῶν Ῥωμαικῶν ἀναγράφων, § 21.

that deity along with the Muses. It is amply illustrated by poetical quotations. In § 24 mention is made of the emperor Vespasian. It is followed by a short treatise entitled *Love Stories*, giving a few narratives of sensational adventures of lovers.

*Short Sayings* (*ἀποφθίγματα*), dedicated to Trajan, extend to a great length, and are divided into three parts:—(1) of kings and commanders (including many Roman); (2) of Spartans; (3) of Spartan women (a short treatise on Spartan institutions being interposed between the last two). The names of the authors are added, and to some of them a large number of maxims are attributed. Many are terse, shrewd, wise, or pointed with strong common-sense; but a good many seem to us now somewhat commonplace.

A rather long treatise *On the Virtues of Women* contains a series of narratives of noble deeds done by the sex in times of danger and trouble, especially from "tyrants." Many of the stories are interesting, and the style is easy and good.

Another long and learned work bears the rather obscure title *Κεφάλαια κατὰ γένος*. It is generally known as *Quæstiones Romanæ* and *Græcæ*, in two parts. In the former, which contains one hundred and thirteen headings, the inquiry (on some matter political, religious, or antiquarian) always commences with διὰ τί, usually followed by πόθεν, with alternative explanations. In the *Greek Questions* the form of inquiry is more often τίς or τίς τις, not followed by πόθεν. This treatise is of great interest and importance to classical archaeology, though the inquiries seem occasionally trifling, and sometimes the answers are clearly wrong.

*Parallels* are a series of similar incidents which occurred respectively to Greeks and Romans, the Greek standing first and the Roman counterpart following. Many of the characters are mythological, though Plutarch regards them as historical.

*On the Fortune of the Romans* discusses whether, on the whole, good luck or valour had more influence in giving the Romans the supremacy. This is followed by two discourses (*λόγοι*) on the same question as applicable to the career of Alexander the Great, *Whether the Athenians were more renowned for War or for Wisdom*. The conclusion is (§ 7) that it was not so much by the fame of their poets as by the deeds of their heroes that Athens became renowned.

*Gryllus* is a most amusing dialogue, in which Circe, Ulysses, and a talking pig take part. Ulysses wishes that all the human beings that have been changed by the sorceress into bestial forms should be restored; but "piggy" is quite opposed to the return, arguing that in moral virtues, such as true bravery, chastity, temperance, and general simplicity of life and contentment, animals are very far superior to man.

*Whether Land Animals or Water Animals are the Cleverer* is a rather long dialogue on the intelligence of ants, bees, elephants, spiders, dogs, &c., on the one hand, and the crocodile, the dolphin, the tunny, and many kinds of fish, on the other. This is a good essay, much in the style of Aristotle's *History of Animals*.

*On Flesh-Eating*, in two orations, discusses the origin of the practice, viz., necessity, and makes a touching appeal to man not to destroy life for mere gluttony (§ 1). This is a short but very sensible and interesting argument. *Questions on Plato* are ten in number, each heading subdivided into several speculative replies. The subjects are for the most part metaphysical; the essay is not long, but it concerns Platonists only. *Whether Water or Fire is more Useful* is also short; after discussing the uses of both elements it decides in favour of the latter, since nothing can exceed in importance the warmth of life and the light of the sun. *On Primary Cold* is a physical speculation on the true nature and origin of the quality antithetical to heat. *Physical Reasons* (*Quæstiones Naturales*) are replies to inquiries as to why certain facts or phenomena occur; e.g., "Why is salt the only flavour not in fruits?" "Why do fishing-nets rot in winter more than in summer?" "Why does pouring oil on the sea produce a calm?" *On the Opinions accepted by the Philosophers*, in five books, is a valuable compendium of the views of the Ionian school and the Stoics on the phenomena of the universe and of life. *On the Manners of Herodotus* is a well-known critique of the historian for his unfairness, not only to the Boeotians and Laedæmonians, but to the Corinthians and other Greek states. It is easy to say that this essay "neither requires nor merits refutation"; but Plutarch knew history, and he writes like one who thoroughly understands the charges which he brings against the historian. The *Lives of the Ten Orators*, from Antipho to Dinarchus, are biographies of various length, compiled, doubtless, from materials now lost.

Two rather long essays, *Should a Man engage in Politics when he is no longer Young*, and *Precepts for Governing* (*πολιτικά παραγγέλματα*), are interspersed with valuable quotations. In favour of the former view the administrations of Pericles, of Agisilaus, of Augustus, are cited (§ 2), and the preference of older men for the pleasures of doing good over the pleasures of the senses (§ 5). In the latter, the true use of eloquence is discussed, and a contrast drawn between the brilliant and risky and the slow and safe policy (§ 10). The choice of friends, and the caution against enmities, the dangers of love, of gain, and of ambition, with many

topics of the like kind, are sensibly advanced and illustrated by examples.

Besides the numerous works that have come down to us, Plutarch speaks of a work called *Africa*, the same title with the lost poem of Callimachus (*Romulus*, § 15).

The *Lives* have often been translated; the most popular version into English is that by John and William Langhorne; more recently many of the Roman lives have been translated, with notes, by the late Mr George Long. An excellent and convenient edition of the Greek text, in 5 vols. 12mo, has been published in the Teubner series by Carl Sintenis. It seems strange that no modern edition of the *Opera Moralia* exists, and that the student has to fall back on the old-fashioned volumes of Wittenbach (6 vols. 4to, Oxford, also printed in 8vo), Reiske (in 12 vols. 8vo), and Hulten (14 vols. 8vo). Whether there is any hope of Rudolph Hercher's single volume (1872) in the Teubner series being followed by others, we have no information. (F. A. P.)

PLUTO, the god of the dead in Greek mythology. His oldest name was Hades (*Αἰδης*, *Αἰδης*, *Ἄδης*), "the Unseen"; the name Pluto (*Πλούτων*) was given him as the bestower of the riches (*πλούτος*) of the mine, and in ordinary language it ousted the dread name of Hades, which was, however, retained in poetry. He was the son of Cronus and Rhea, and brother of Zeus and Poseidon. Having deposed Cronus, the brothers cast lots for the kingdoms of the heaven, the sea, and the infernal regions, and Pluto obtained the infernal regions, which from their ruler were afterwards known as Hades. The "house of Hades" was a dark and dreadful abode deep down in the earth. How literally the god was supposed to dwell underground is shown by the method of invoking him, which was by rapping on the ground to attract his attention. According to another view the realm of Hades was in a land beyond the ocean in the far west, which to the Greek was always the region of darkness and death, as the east of light and life. This is the view of Hades presented in the *Odyssey*. Ulysses sails all day with a north wind, and at sunset reaches a land at the limits of ocean. Here, wrapped in mist and cloud, dwell the Cimmerians, who never see the sun. He lands, and moving along the shore he calls the ghosts of the departed to meet him. In the description of the Cimmerians we have perhaps a traveller's tale of the long dark winters of the north. Besides this gloomy region, we find in another passage of the *Odyssey* (iv. 561 sq.) a picture of Elysium, a happy land at the ends of the earth, where rain and snow fall not, but the cool west wind blows and men live at ease. After Homer this happy land, the abode of the good after death, was known as the Islands of the Blest, and these in later times were identified with Madeira and the Canary Islands.<sup>1</sup> But in the oldest Greek mythology the "house of Hades" was a place neither of reward nor punishment; it was simply the home of the dead, good and bad alike, who led a dim and shadowy reflexion of life on earth. The differentiation of this "home of Hades" into a heaven and a hell was the result of progressive thought and morality. Pluto was himself simply the ruler of the dead; in no sense was he a tempter and seducer of mankind like the devil of Christian theology. Indeed the very conception of a devil, as a principle of evil in continual conflict with God or the principle of good, is totally foreign to Greek mythology, as it was also to Indian and Teutonic mythology. Pluto was certainly depicted as

<sup>1</sup> The conception of the land of the dead, whether in the far west or beneath the earth, might be paralleled from the beliefs of many savage tribes. The Samoan Islanders unite the two conceptions: the entrance to their spirit-land is at the westernmost point of the westernmost island, where the ghosts descend by two holes into the under-world. Long ago the inhabitants of the French coast of the English Channel believed that the souls of the dead were ferried across to Britain, and there are still traces of this belief in the folk-lore of Brittany (Tylor, *Primitive Culture*, ii. p. 64; Grimm, *Deutsche Mythologie*, ii. p. 694). In classical mythology the underground Hades prevailed over the western. It was an Etruscan custom at the foundation of a city to dig a deep hole in the earth, and close it with a stone; on three days in the year this stone was removed, and the ghosts were then supposed to ascend from the lower world. In Asia Minor caves filled with mephitic vapours or containing hot springs were known as Plutonia or Charonia. The most famous entrances to the under-world were at Tænarum in Laconia, and at the Lake Avernus in Italy.

stern and pitiless, but he was so only in discharge of his duty as custodian of the dead. But even Pluto once melted at the music of Orpheus when he came to fetch from the dead his wife Eurydice. The cap of Hades, like the *Nebelkappe* of German mythology, rendered its wearer invisible; as a sort of thick clond it was the reverse of the nimbus or halo of the heavenly gods. While the victims sacrificed to the latter were white, those offered to Pluto were black. His wife was Proserpine (*Persephone*), daughter of Demeter (*Ceres*), whom he carried off as she was gathering flowers at Enna in Sicily. Like the Greeks, the ancient Italians believed that the souls of the dead dwelt underground; in Latin the names for the god of the dead are Orcus and Father Dis, but the Greek name Pluto also frequently occurs. But, while Orcus was rather the actual slayer, the angel of death, Father Dis was the ruler of the dead, and thus corresponded to Pluto. Their names also correspond, Dis being a contraction for Dives, "wealthy." The Etruscan god of death was represented as a savage old man with wings and a hammer; at the gladiatorial games of Rome a man masked after this fashion used to remove the corpses from the arena. In Romanesque folklore Orcus has passed into a forest-elf, a black, hairy, man-eating monster, upon whose house children lost in the woods are apt to stumble, and who sometimes shows himself kindly and helpful. He is the Italian *orco*, the Spanish *ogro*, the English *ogre*.

PLUTUS (*πλοῦτος*, "wealth"), the Greek god of riches, whom Demeter bore to Iasion "in the fat land of Crete." He enriched every one whom he fell in with. According to Aristophanes, he was blinded by Zeus in order that he might not enrich the good and wise alone. At Thebes there was a statue of Fortune holding the child Plutus in her arms; at Athens he was similarly represented in the arms of Peace; at Thespiae he was represented standing beside Athene the Worker. Elsewhere he was represented as a boy with a cornucopia. He is the subject of one of the extant comedies of Aristophanes.

PLYMOUTH, a municipal and parliamentary borough and seaport town of Devonshire, England, is picturesquely situated on Plymouth Sound in the south-west corner of the county, at the confluence of the Tamar and Plym, 44 miles south-west of Exeter. With the borough of Devonport and the township of East Stonehouse it forms the aggregate town known as the "Three Towns." There is railway communication by means of the Great Western and South-Western lines, and by several branch lines connected with these systems. The defences of the town, in addition to the citadel, an obsolete fortification built by Charles II., on the site of an older fort, consist of a most elaborate chain of forts of great strength mounted with guns of the heaviest calibre, and forming a complete line of defence round the whole circumference both landwards and seawards. The streets are for the most part narrow and crooked, and the houses very irregular both in style of architecture and in height. Great improvements have, however, recently taken place. The more ancient part of the town near the water-side has been much altered, and a number of model dwellings have also lately been erected. In the principal thoroughfares there are numerous handsome shops and other imposing business establishments. Among the most important of the public buildings is the Guildhall, completed in 1874 at a cost of £56,000, a fine

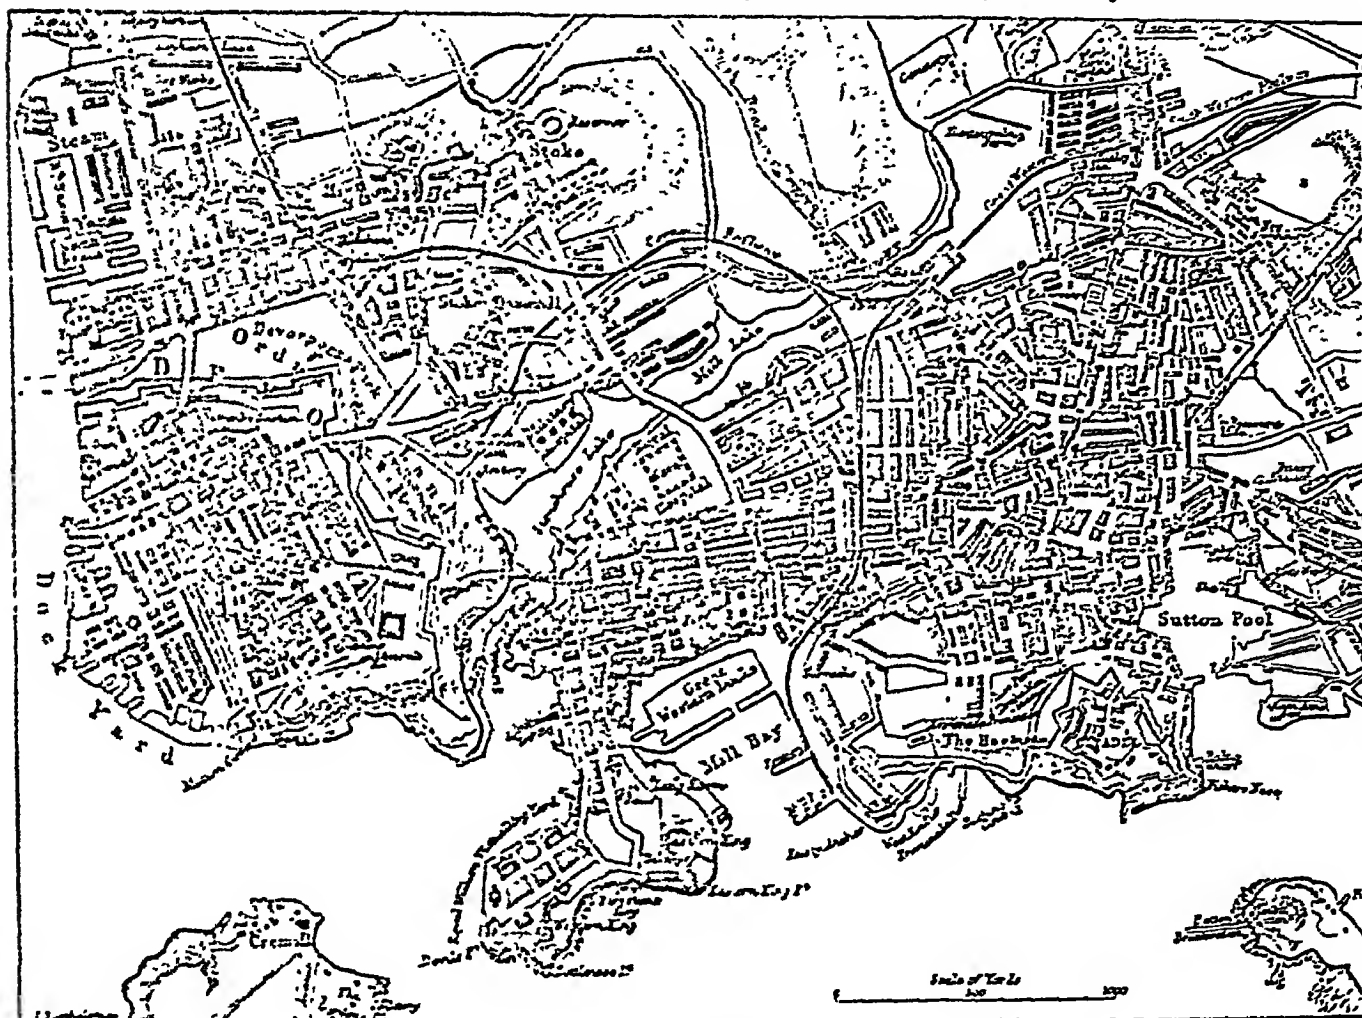

Environs of Plymouth.

group in the Gothic style of the 13th century, with a lofty tower, and containing the town-hall with a fine organ and a series of historical windows, a police court and offices, a sessions and other court rooms, and the council chamber and municipal offices. The new post office in Westwell Street was erected at a cost of £12,000. The market, dating from 1804, and occupying about three acres in the centre of the town, is in course of reconstruction. A fine clock-tower, erected by the corporation, stands at the junction of George Street and Union Street. The parish church of St Andrews, some portions of which date from about 1430, has undergone alterations and improvements at different periods, and in 1874-75 was completely restored under the direction of the late Sir G. G. Scott. The tower, built in 1460, contains a fine peal of bells. The church of Charles the Martyr was begun in 1640, when the parish was divided, but owing to the Civil War was not completed till 1657. Of the other more modern parish churches there are none of special interest. The town is the seat of a Roman Catholic bishopric, the cathedral of which, a good building in the Early English style, was opened in 1858 at a cost of £10,000. Attached to it is the convent of Notre Dame, and several other religious houses and chapels. The Athenæum (1812) is the home of the Plymouth Institution and the Devon and Cornwall Natural History Society. In connexion with it there are a lecture hall, a museum, art gallery, and a small but select scientific library. The Plymouth Proprietary Library (1812) has a good selection of books in general literature, and the building also contains the library of the Plymouth Incorporated Law Society and the Cottonian collection, which includes many relics of Sir Joshua Reynolds and a number of his pictures. The Free Public Library, established in 1876, at present occupies the old Guildhall. The principal educational establishments are the Western College for the training of students for the ministry of the Independent denomination; the Plymouth College, a high school for boys; the High School for Girls; the Corporation Grammar School, founded in 1572; the Public School, established in 1809 (one of the largest public schools in England); the Grey Coat School; the Blue Coat School; the Orphan's Aid; Lady Rogers's School; the Orphan Asylum; and the Household of Faith founded by the well known Dr Hawker. The Plymouth school board has nine schools in full operation; and each of the principal parishes has also its parochial day school. The charitable institutions embrace the South Devon and East Cornwall Hospital, for which a fine range of buildings has lately been erected; the Devon and Cornwall Female Orphan Asylum (1834); the Penitentiary and Female Home (1833); the Royal Eye Infirmary (1821); the South Devon and Cornwall Institution for the Blind (1860, new building erected 1876), and various other philanthropic societies. The only public recreation ground of any extent is the Hoe Park, 18 acres, a fine promenade sloping gradually to the sea, attached to which is a handsome promenade pier. On the Hoe a statue in bronze, by Boehm, of Sir Francis Drake was unveiled in 1884. Smeaton's lighthouse has been removed from the reef on which it stood for one hundred and twenty years, and is now a prominent object on the Hoe. The view from the Hoe includes Mount Edgecumbe with its beautifully wooded slopes, the Cornwall hills, the Dartmoor hills on the north-eastern horizon, and Eddystone lighthouse far away over the waters of the Channel.

Plymouth not only holds a leading position in the country as a naval station, but is the centre of the growing trade of Devonshire and Cornwall, and is also becoming a holiday centre and health resort. To the south of the town is the Sound, protected by the magnificent break-water, within the limits of which and the harbours con-

nected with it the whole British navy might find a safe anchorage. The western harbour, known as the Hamoaze, at the mouth of the river Tamar, is devoted almost exclusively to the requirements of the royal navy, as along its banks are the dockyard, the Keyham factory, the arsenal, and other Government establishments (See *DEVONPORT*, vol. vii., 138; and *DOCKYARDS*, vol. vii., 315). The eastern harbour, Cattewater with Sutton Pool, now protected by a new breakwater at Mount Batten, is the anchorage ground for merchant shipping. Commodious dock accommodation is provided at the Great Western Docks, Millbay, between Plymouth and Stonehouse, opened in 1857, and comprehending a floating basin over 13 acres in extent with a depth of 22 feet at spring tides, a tidal harbour of 35 acres, and a graving dock. The port has an extensive trade with America, the West Indies, Mauritius,

Africa, and the Baltic ports, as well as an extensive coasting trade. It is the starting point for many of the emigrant ships for Australia, New Zealand, and British America. The chief exports are minerals, including copper, lead, tin, granite, and marble. There is also some trade in pilchards and other fish. The imports are chiefly agricultural produce and timber. The total number of vessels that entered the port in cargo and in ballast in 1883 was 3852, of 843,227 tons, the number that cleared 3443, of 754,318 tons. Plymouth has few manufactures, the principal being biscuits, black-lead, candles, manures, soap, starch, sugar, lead, and the celebrated Plymouth gin. The principal industries are connected with shipbuilding and the fisheries. According to the Act of 1835, the borough is divided into six wards, and is governed by a mayor, twelve aldermen, and thirty-six councillors. The

Plan of Plymouth.

water-works are under the control of the corporation, but the gas works are in the hands of a company. The population of the municipal borough (area 1468 acres) in 1871 was 68,758, and in 1881 it was 73,794. The population of the parliamentary borough (area 2061 acres) in the same years was 70,091 and 76,060. It returns two members to parliament.

The Hoe at Plymouth is claimed to be the high rock from which, according to Geoffrey of Monmouth, Corineus the Trojan hurled the giant Goemagot into the sea, and at an early period there was cut out in the ground at the Hoe the likenesses of two figures with clubs in their hands, which for many years was renewed by the corporation, and was in existence till the erection of the citadel about 1671. Both British and Roman remains have been found in the neighbourhood, the most important being those of a Romano-British cemetery discovered in 1862 during the construction of Fort Stamford. In Domesday it occurs as Sutone, and afterwards it was divided into the town of Sutton Prior, the hamlet of Sutton Valletort, and the tithing of Sutton Ralph, a part of it having been granted to the Norman family of Valletort, while the greater part belonged to the

priory of Plympton. About 1253 a market was established, and in 1292 the town first returned members to parliament. In the 14th century it was frequently the port of embarkation and of disembarkation in connexion with expeditions to France. It suffered considerably at the hands of the French in 1338, 1350, 1377, 1400, and 1402, the Bretons on the last occasion destroying six hundred houses. In 1412 the inhabitants petitioned for a charter, but for a long time their application was opposed by the prior and convent of Plympton. In 1439 a charter was, however, at last granted by Henry VI., defining the limits of the town, permitting the erection of walls and defences, allowing the levying of dues on shipping for the purpose of such buildings and their maintenance, and directing the institution of a corporate body under the title of the "mayor and commonalty of the borough of Plymouth." Leland speaks (1540-47) of Plymouth harbour as being chained across in times of necessity, and of an "old 'castel quadrat' between the town and the sea." A small fragment of one of the outer works of this castle still stands at the foot of Lambhay Street. During the rebellion of 1548-49 the town suffered severely at the hands of the insurgents, and according to Westcote the "evidences" of the borough were burnt. Under Elizabeth it rose to be the foremost port of England, and Camden, who visited the town about 1588,

states that "though not very large its name and reputation is very great among all nations." In the discovery of the New World it played a part of prime importance. Martin Cockeram, a native of the town, sailed with Sebastian Cabot when he touched the coast of America in 1497. Sir John Hawkins and his father William were natives of the town, and in 1571 Sir John was returned member of parliament for the borough. In 1572 Sir Francis Drake left the port for the West Indies, and in 1577 he set out from it on his voyage "about the earth." He was elected mayor of the town in 1581, and in 1592-93 represented it in parliament. Sir Humphrey Gilbert, who was M.P. for Plymouth in 1571, had in 1578 received from Queen Elizabeth letters patent for a colony in America; but, after setting out in 1579, he was compelled to return with the loss of his principal ship. In 1583 he sailed again from Plymouth (see GILBERT). In 1585 Drake again sailed from Plymouth for the West Indies, bringing back on his return the remnant of Raleigh's Virginian colony. The port supplied seven ships against the Spanish Armada, and it was in the Sound that the English fleet of 120 sail awaited the sighting of the Spaniards. In 1590 Drake was successful in the oft attempted task of bringing in a stream of fresh water for the use of the town, from the river Meavy near Sheepstor, Dartmoor. He and Sir John Hawkins sailed from Plymouth on their last voyage in 1595, both dying at sea in the following year. Many other expeditions from Drake's time to the present have been despatched from this port, which was the last at which the Pilgrim Fathers touched when they set sail for America. Plymouth was throughout nearly the whole Civil War closely invested by the Royalists, and was the only town in the west of England which never fell into their hands. The town was one of the first to declare for William of Orange. It was in 1691, during his reign, that the dockyard was commenced. The "local literature" of Plymouth is singularly rich and comprehensive. It has also a connexion with many men of great eminence. Sir Joshua Reynolds, born at Plympton, first practised his art in the town, and its native artists are represented by Sir Charles Lock Eastlake, James Northcote, Benjamin Robert Haydon, and Samuel Prout. Besides Sir John Hawkins and other celebrated seamen, it has also given birth to Sir William Snow Harris, Dr James Yonge, Dr John Kirto, Dr S. P. Tregelles, Dr Robert Hawker, N. T. Carrington the Dartmoor poet, Mortimer Collins, and Sir R. P. Collier.

PLYMOUTH, a township and village of the United States, the shire-town of Plymouth county, Massachusetts, and a port of entry on Cape Cod Bay,—the village lying at the terminus of a branch of the Old Colony Railroad, 37 miles south-south-east of Boston. The main interest of Plymouth is historical, and centres in the fact that it was the first settlement of the Pilgrim Fathers of New England, who landed December 21 (N. S.), 1620, on the rock now covered by a handsome granite canopy in Walter Street. Leyden Street, so called in memory of the Dutch town where the exiles had stopped for a season, is the oldest street in New England. The houses and general appearance of Plymouth are, however, thoroughly modern. Pilgrim Hall (which is built of granite and measures 70 feet long by 40 feet wide) was erected in 1824-25 by the Pilgrim Society constituted in 1820; it contains a public library and many relics of the fathers—including Miles Standish's sword and Governor Carver's chair. The corner stone of a national monument to the Pilgrims was laid August 1, 1859, on a high hill near the railroad station; 1500 tons of granite were used for the foundation; and a pedestal 45 feet high is surrounded by statues 20 feet high of Morality, Law, Education, and Freedom, and bears a colossal statue of Faith, 36 feet high, holding a Bible in her right hand (the largest granite statue in the world). Burying Hill was the site of the embattled church erected in 1622, and contains many ancient tombstones and the foundations of the watchtower (1643) now covered with sod. Cole's Hill is the spot where half of the "Mayflower" Pilgrims found their rest during the first winter. Five of their graves were discovered in 1855 while pipes for the town water-works were being laid, and two more (now marked with a granite slab) in 1883. The bones of the first five are deposited in a compartment of the canopy over the "Forefathers' Rock." A town hall (1749), the county

court-house, and the house of correction are the main public buildings of Plymouth. The population of the township was 4758 in 1830, 6024 in 1850, 6238 in 1870, 7093 in 1880, and 7500 in 1884. Manufactures of sail-duck, cotton-cloth, tacks, nails, plate-iron, rolled zinc and copper rivets, hammers, &c., are carried on; the cordage factories are among the largest and most complete works of the kind in the world.

PLYMOUTH, a borough of the United States, in Luzerne county, Pennsylvania, on the Bloomsburg division of the Delaware, Lackawanna, and Western Railroad, 8 miles from Wyoming, is a flourishing coal-mining town, which increased its population from 2648 in 1870 to 6065 in 1880. At Plymouth junction, 2 miles to the north-east, a branch line to Wilkesbarre connects with the Central Railroad.

PLYMOUTH BRETHREN, or BRETHREN, are a community of Christians who received the name in 1830 when the Rev. J. N. Darby induced many of the inhabitants of Plymouth to associate themselves with him for the promulgation of his opinions. Although small Christian communities existed in Ireland and elsewhere calling themselves *Brethren* and holding similar views, the accession to the ranks of Mr Darby so increased their numbers and influence that he is usually reckoned the founder of Plymouthism. Darby (born in Nov. 1800, in London; graduated at Trinity College, Dublin, in 1819; died April 29, 1882, at Bourne-mouth) was a curate in the Episcopal Church of Ireland until 1827, when he felt himself constrained to leave the Established Church; betaking himself to Dublin, he became associated with several devout people who met stately for public worship, and called themselves "Brethren." In 1830 Darby at Plymouth won over a large number of people to his way of thinking, among whom were the Rev. James L. Harris, a Plymouth clergyman, and the well-known Biblical scholar Dr Samuel Prideaux Tregelles. The Brethren started a periodical, *The Christian Witness*, continued from 1849 as *The Present Testimony*, with Harris as editor and Darby as the most important contributor. During the next eight years the progress of the sect was rapid, and communities of the brethren were to be found in many of the principal towns in England.

In 1838 Darby went to reside in French Switzerland, and found many disciples. Congregations were formed in Geneva, at Lausanne, where most of the Methodist and other dissenters joined the Brethren, at Vevey, and elsewhere in Vaud. His opinions also found their way into France, Germany, German Switzerland, and Italy; but French Switzerland has always remained the stronghold of Plymouthism on the Continent, and for his followers there Mr Darby wrote two of his most important tracts, *Le Ministère considéré dans sa Nature* and *De la Présence et de l'Action du S. Esprit dans l'Eglise*. The revolution in the canton Vaud, instigated by the Jesuits in 1845, brought persecution to the Brethren in the canton and in other parts of French Switzerland, and Darby felt his own life insecure there.

He returned to England, and his reappearance was accompanied by divisions among the Brethren at home. These divisions began at Plymouth. Mr Benjamin Wills Newton, at the head of the community there, who had been a fellow of Exeter College, Oxford, was accused of departing from the testimony of the Brethren by reintroducing the spirit of clericalism. Unable to detach the congregation from the teacher, Darby began a rival and separate assembly. The majority of the Brethren out of Plymouth supported Darby, but a minority kept by Newton. The separation became wider in 1847 on the discovery of supposed heretical teaching by Newton. In 1848 another division took place. The Bethesda congre-

gation at Bristol, where Mr George Müller was the most influential member, received into communion several of Newton's followers and justified their action. A large number of communities approved of their conduct; others were strongly opposed to it. Out of this came the separation into Neutral Brethren, led by Müller, and Exclusive Brethren or Darbyites, who refused to hold communion with the followers of Newton or Müller. The Exclusives, who were the more numerous, suffered further divisions. An Irish clergyman named Cluif had adopted views similar to those of Mr Pearsall Smith, and when these were repudiated seceded with his followers. The most important division among the Exclusives came to a crisis in 1881, when Mr William Kelly and Mr Darby became the recognized leaders of two sections who separated on a point of discipline. This was followed (1885) by the disruption of the strict Darbyite section, two communities being formed out of it upon points of doctrine. There are therefore now six sections of Plymouthists:—(1) the followers of Mr B. W. Newton; (2) the Neutrals, who incline to the Congregationalist idea that each assembly should judge for itself in matters of discipline, headed by Mr George Müller; (3) the Exclusives who claim to be the original Brethren, and are represented by Messrs J. B. Stoney and C. H. Mackintosh; (4) the Exclusives associated in Great Britain with Mr C. E. Stuart, in America with Mr F. W. Grant; (5) the Exclusives who follow Mr Kelly; and (6) the Exclusives who follow Mr Cluif. The fundamental principle of the Exclusives, "Separation from evil God's principle of unity," has led to many unimportant excommunications and separations besides those mentioned.

The theological views of the Brethren differ considerably from those held by evangelical Protestants (for a list of divergences, see Teulon, *History and Doctrines of the Plymouth Brethren*). They make the baptism of infants an open question and celebrate the Lord's Supper weekly. Their distinctive doctrines are ecclesiastical. They hold that all official ministry, anything like a clergy, whether on Episcopalian, Presbyterian, or Congregationalist theories, is a denial of the spiritual priesthood of all believers, and sets aside the Holy Spirit's guidance. The gradual growth of this opinion, and perhaps the reasons for holding it, may be traced in Mr Darby's earlier writings. While a curate in the Church of Ireland he was indignant with Archbishop Magee for stopping the progress of mission work among Roman Catholics by imposing on all who joined the church the oath of supremacy. This led Darby to the idea that established churches are as foreign to the spirit of Christianity as the papacy is ("Considerations addressed to the Archbishop of Dublin, &c.," *Coll. Works*, vol. i. 1). The parochial system, when enforced to the extent of prohibiting the preaching of the gospel within a parish where the incumbent was opposed to it, led him to consider the whole system a hindrance to the proper work of the church and therefore anti-Christian ("Thoughts on the present position of the Home Mission," *Coll. Works*, i. 78). And the waste of power implied in the refusal to sanction lay preaching seemed to him to lead to the conclusion that an official ministry was a refusal of the gifts of the Spirit to the church ("On Lay Preaching," *Coll. Works*, p. 200). The movement, if it has had small results in the formation of a sect, has at least set churches to consider how they might make their machinery more elastic. Perhaps one of the reasons of the comparatively small number of Brethren may be found in their idea that their mission is not to the heathen but to "the awakened in the churches."

**PNEUMATIC DESPATCH.** The transport of written despatches through long narrow tubes by the agency of air-pressure was introduced in 1853, by Mr Latimer Clark, between the Central and Stock Exchange stations of the Electric and International Telegraph Company in London. The stations were connected by a tube  $1\frac{1}{2}$  inches in diameter and 220 yards long. Carriers containing batches of telegrams, and fitting piston-wise in the tube, were sucked through it (in one direction only) by the production of a partial vacuum at one end. In 1858 Mr C. F. Varley improved the system by using compressed air to force the carriers in one direction, a partial vacuum being still used to draw them in the other direction. This improvement enables single radiating lines of pipe to be used both for sending and for receiving telegrams between a central station supplied with pumping machinery and outlying stations not so supplied. In the hands of Messrs Culley and Sabine this radial system of pneumatic despatch has been brought to great perfection in connexion with the telegraphic department of the British post office. Another method of working, extensively used in Paris and other Continental cities, is the circuit system, in which stations are grouped on circular or loop lines, round which carriers travel in one direction only. In one form of circuit system—that of Messrs Siemens—a continuous current of air is kept up in the tube, and rocking switches are provided by which carriers can be quickly introduced or removed at any one of the stations on the line without interfering with the movement of other carriers in other parts of the circuit. More usually, however, the circuit system is worked by despatching carriers, or trains of carriers, at relatively long intervals, the pressure or vacuum which gives motive power being applied only while such trains are on the line. On long circuits means are provided at several stations for putting on pressure or vacuum, so that the action may be limited to that section of the line on which the carriers are travelling at any time.

The following particulars refer to the radial system of pneumatic despatch as used in the British post office. In London most of the lines connect the central office with district offices for the purpose of collecting and distributing telegrams. Iron tubes were used in some of the earliest lines, but now the tubes are always made of lead, with soldered joints, and are enclosed in outer pipes of iron for the sake of mechanical protection. The bore, which is very smooth and uniform, is normally  $2\frac{1}{2}$  inches, though in a few cases it is as much as 3 inches, and in some only  $1\frac{1}{2}$  inches. The greatest single length of any of the existing London lines is 3573 yards, but a more usual length is from 1000 to 2000 yards. In most cases a single tube serves both to send and to receive, but where the traffic is heavy a pair of tubes are used, one to send by pressure and the other to receive by vacuum. The pumps, which supply pressure and vacuum to two mains, are situated in the central office. At the outlying stations the tubes terminate in a glass box, open to the atmosphere. At the central station the end of each tube is a short vertical length, facing downwards, and provided with a double valve, consisting of two sluices, one at the end and the other a little way above the end, the distance between the sluices being somewhat longer than the length of a carrier. The sluices are geared together in such a manner that a single movement of a handle closes one and opens the other, or *vice versa*. To send a carrier from the central station, the carrier is introduced into the tube, the lower sluice being open; a single movement of the handle then successively (1) closes the lower sluice, (2) opens the upper sluice, and (3) opens a valve which admits air behind the carrier from the compressed-air main. As soon as the arrival of the carrier is signalled (electrically) from the out-station, the handle is pushed back, thus (1) cutting off the compressed air, (2) closing the upper sluice, and (3) opening the lower sluice. The tube is then ready for the sending of another carrier. When an electric signal arrives from an out-station that a carrier is inserted there for transmission to the central station the handle is pulled for-

ward far enough to close the lower and open the upper sluice, but not far enough to put on the air-pressure. The vacuum main is then put in connexion with the tube by a separate stop-cock. When the carrier arrives the vacuum is shut off and the lower sluice opened to allow it to drop out. This arrangement of double sluices admits of the insertion or removal of a carrier while other carriers are travelling in the same tube, and without sensible disturbance of their motion. But great caution requires to be exercised in allowing two or more carriers to follow one another on a single section of line, especially on lines worked by pressure, since no two carriers travel at precisely the same speed. When the same tube is used alternately for sending and receiving the upper sluice is dispensed with. On some lines there are intermediate stations, and the sections are then worked by a block system like that used on railways. The carriers are cylindrical cases of gutta-percha covered with felt, which is allowed to project loosely at the back, so that the pressure makes it expand and fit the pipe closely. In front the carrier is closed by a buffer or piston composed of disks of felt of the diameter of the pipe. The despatches are held in by an elastic band at the back. An ordinary carrier weighs 2½ oz., and holds about a dozen despatches. During business hours carriers are passing through the London tubes almost incessantly. With a pressure of 10 lb per square inch, or a vacuum of 7 lb, the time of transit, if through a 2½ inch tube, is 1 minute for a length of nearly 1000 yards, and 5½ minutes for a length of 3000 yards.

The following statistics show the growth of the pneumatic despatch in the post office during ten years (the figures for 1875 are taken from a paper by Messrs Culley and Sabine, cited below, and those for 1885 have been furnished by Mr W. H. Precco):—

	January 1875.		January 1885.	
	No. of Tubes.	Total Length.	No. of Tubes.	Total Length.
		Miles. Yards.		Miles. Yards.
London.....	25	17 1160	82 <sup>1</sup>	33 635

Total.....	41	21 1242	108	40 1239

<sup>1</sup> Including 29 short "house" tubes.

In Paris large areas of the city have been covered by pneumatic circuits made up of iron pipes round which omnibus trains of carriers are sent at intervals of fifteen minutes. The trains consist of several carriers much heavier than the English type, linked to one another and to a leading piston. The trains are stopped at the successive stations to take up and deposit despatches. The pneumatic despatch took root in Paris in 1866, and has been developed there in a way which differs greatly in mechanical details from the English system. An arrangement like that used in Paris has been followed in Vienna and in Berlin, where the Siemens system has also been used. In New York the English system is adopted, but with brass instead of lead tubes.

Interruptions occurring in the pipes can be localized by firing a pistol at one end and registering by a chronograph the interval of time between the explosion and the arrival of the air-wave reflected from the obstacle.

In addition to its use for postal and telegraphic purposes the pneumatic despatch is occasionally employed for internal communication in offices, hotels, &c., and also in shops for the transport of money and bills between the cashier's desk and the counters.

*References.*—The system as now used in the United Kingdom is fully described in a paper by Messrs Culley and Sabine (*Min. Proc. Inst. Civ. Eng.*, vol. xiii.). The same volume contains a description of the pneumatic telegraphs of Paris and of experiments on them by M. Bontemps, and also a discussion of the theory of pneumatic transmission by Prof. W. C. Unwin. Reference should also be made to a paper by G. Siemens (*Min. Proc. Inst. Civ. Eng.*, vol. xxxiii.) describing the Siemens circuit system; and to *Les Télégraphes*, by M. A. L. Ternant (Paris, 1881).

(J. A. E.)

**PNEUMATICS** is that department of hydrodynamics which treats of the properties of gases as distinct from liquids. Under **HYDROMECHANICS** will be found a general discussion of the subject as a branch of mathematical physics; here we shall limit our attention mainly to the experimental aspect.

The gaseous fluid with which we have chiefly to do is our atmosphere. Though practically invisible, it appeals in its properties to other of our senses, so that the evidences of its presence are manifold. Thus we feel it in its motion as wind, and observe the dynamical effects of this motion in the quiver of the leaf or the momentum of

the frigate under weigh. It offers resistance to the passage of bodies through it, destroying their motion and transforming their energy—as is betrayed to our hearing in the whizz of the rifle bullet, to our sight in the flash of the meteor. In its general physical properties air has much in common with other gases. It is advisable therefore first to establish these general properties, and then consider the characteristic features of the several gases.

Matter is conveniently studied under the two great Solid and divisions of solids and fluids. The practically obvious fluid distinction between these may be stated in dynamical language thus:—solids can sustain a longitudinal pressure without being supported by a lateral pressure; fluids cannot. Hence any region of space enclosed by a rigid boundary can be easily filled with a fluid, which then takes the form of the bounding surface at every point of it. But here we distinguish between fluids according as they are gases or liquids. The gas will always completely fill the region, however small the quantity put in. Remove any portion and the remainder will expand so as to fill the whole space again. On the other hand it requires a definite quantity of liquid to fill the region. Remove any portion and a part of the space will be left unoccupied by liquid. Part of the liquid surface is then otherwise conditioned than by the form of the wall or bounding surface of the region; and if the portion of the wall not in contact with the liquid is removed the form and quantity of the liquid are in no way affected. Hence a liquid can be kept in an open vessel; a gas cannot so be.

The mutual action between any two portions of matter Stress, is called the stress between them. This stress has two aspects, according as its effect or tendency is considered with reference to the one or the other body. Thus between the earth and moon there is a stress which is an attraction. The one aspect is the force which attracts the moon to the earth; the other is the force which attracts the earth to the moon. According to Newton's third law of motion these are equal and opposite. Similarly the repulsive stress between the like poles of two magnets has its two aspects, which are equal but oppositely directed forces. In the case of a mass hanging by a cord, the stress is a tension at every point of the cord. At any given point this tension has two equal and opposite aspects, one of which is the weight of the mass and the portion of the cord below the given point. Finally, the stress between any body and the horizontal table on which it rests is a two-faced pressure, being downwards as regards the table, upwards as regards the body. The total pressure upon the table over the whole surface of contact is clearly the weight of the body. If the total pressure is supposed to be uniformly distributed, the measure of the pressure on unit surface is the quotient of this weight by the area of the surface. When we speak of pressure at a point, it is this pressure on unit surface that is meant. When the pressure varies from point to point over a surface, the pressure at any point is defined to be the limit of the ratio of the total pressure over any small element of surface around that point to the area of the element as the element is diminished indefinitely.

The stress which exists between the contiguous portions of a fluid is of the nature of a pressure. The ideal or perfect fluid is a substance in which this stress between contiguous portions is always perpendicular to the common interface. In other words there is no stress tangential to the interface at any point. Hence if the contiguous portions are at relative rest, or have a relative motion parallel to the interface, neither state can be affected by the mutual stress. This condition is perfectly fulfilled in the case of any known fluid in equilibrium; but for a fluid in motion it is not even approximately fulfilled. For, any

Ideal perfect fluid defined.

visible relative motion set up among the parts of a fluid rapidly decays in virtue of viscosity, which even for the subtlest gases is quite appreciable in its effects.

In a fluid at rest, then, the pressure over any surface which we may imagine to be drawn is perpendicular (or normal) to the surface at every point of it; and from this it follows at once, as has been proved in *HYDROMECHANICS*, vol. xii. p. 439, that *the pressure at any point of a fluid at rest has the same value in all possible directions.*

**Level surface.** The pressures at two contiguous points in a fluid may either differ or not. If they differ, the change of pressure must be balanced by some extraneous force acting on the fluid in the direction in which the pressure increases. Any direction in which no such force acts must be a direction in which there is no change of pressure; otherwise, equilibrium will be destroyed. Suppose now the resultant force at every point in a fluid at rest to be given. In directions at right angles to the force at any given point the pressure will not vary. Hence we can pass to an infinite number of contiguous points at which the pressure is the same as at the given point. By making each of these in turn the starting-point, we can pass on to another set of points, and so gradually trace out within the fluid a surface at every point of which the pressure is the same. Such a surface is called a surface of equal pressure, or briefly a level surface: and we see from the mode of its construction that it is at every point of it perpendicular to the resultant force at that point.

Imagine any two contiguous level surfaces to be drawn, at every point of the one of which the pressure is  $p$ , at every point of the other  $p + \delta p$ . Consider the equilibrium of a small column of average density  $\rho$ , bounded at its ends by these surfaces. Let  $A$  be the area of each end, and  $dr$  the length of the column or perpendicular distance between the level surfaces. If  $R$  is the average resultant force per unit mass acting on the column, then we have, for equilibrium of the column,

$$A\delta p = A\delta r \cdot \rho R, \\ \delta p = R\delta r.$$

or *the rate of increase of the pressure at any point per unit of length at right angles to the level surface is equal to the resultant force per unit of volume at that point.*

If the applied forces belong to a conservative system, for which  $V$  is the potential (see *MECHANICS*), we may write the equation in the form

$$\delta p = -\rho \delta V.$$

**Equipotential surfaces.** Hence over any equipotential surface, for which  $\delta V = 0$ ,  $p$  is constant, and is therefore a function of  $V$ . Consequently  $\rho$  also is a function of  $V$ . For a fluid in equilibrium, therefore, and under the influence of a conservative system of forces, the pressure and density are constant over every equipotential surface, that is, over every surface cutting the lines of force at right angles.

Now in the case of gases, to which our attention is at present confined, the density (temperature remaining constant) varies with every change of pressure; in mathematical language  $\rho$  is a function of  $p$ . Thus, before we can solve the equation of equilibrium for a gas, we must be able to express this function mathematically; in other words, we must know the exact relation between the density of a gas and the pressure to which it is subject. This problem, which can only be settled by experiment, was solved for the case of air within a certain range of pressures by Robert Boyle (1662). Before discussing his results and the later results of other investigators, we shall first consider the general properties of our atmosphere as recognized before Boyle's day.

It is evident that, for a fluid situated as our atmosphere is, the pressure must diminish as we ascend. The equi-

potential surfaces and consequently the surfaces of equal pressure and of equal density will be approximately spheres concentric with the earth. At any point there will be a definite atmospheric pressure, which is equal numerically to the weight of the superincumbent vertical column of air of unit cross-section. The effect of this pressure, as exemplified in the action of the common suction-pump, seems to have been first truly recognized by Galileo, who showed that the maximum depth from which water can be pumped is equal to the height of the water column which would exert at its base a pressure equal to the atmospheric pressure. As an experimental verification, he suggested filling with water a long pipe closed at the upper end, and immersing it with its lower end open in a reservoir of the same liquid. The liquid surface in the pipe would, if the pipe were long enough, stand at a definite height, which would be the same for all longer lengths of pipe. The practical difficulty of constructing a long enough tube (33 feet at least) prevented the experiment being really made till many years later.

Torricelli, however, in 1642, by substituting mercury for water, produced the experiment on a manageable scale. As *mercury is denser than water in the ratio of about 13.6:1*, the mercury column necessary to balance by its weight the atmospheric pressure will be less than the water column in the inverse ratio, or a little under 30 inches. Torricelli's experiment is exhibited in every mercurial barometer (see *BAROMETER and METEOROLOGY*). By this experiment he not only gave the complete experimental verification of Galileo's views relating to atmospheric pressure, but provided a ready means of measuring that pressure.

The most obvious applications of the barometer are these:—(1) to measure the variation in time of atmospheric pressure at any one locality on the earth's surface (the existence of this variation was discovered soon after the date of Torricelli's experiment by Pascal, Descartes, Boyle, and others); (2) to measure the variation of atmospheric pressure with change of height above the earth's surface (Descartes mentions this application in the *Principia Philosophiæ*, 1644; but to Pascal is the honour due of having first carried the experiment into execution, 1647); and (3) to compare pressures at different localities which are on the same level (if the pressures are equal, the air is in equilibrium; if they are not, there must be flow of air from the place of higher pressure to that of lower—in other words, there must be wind, whose direction of motion depends on the relative position of the places, and whose intensity depends on the distance between the places, and the difference of pressures). The first and last of these measurements are of the greatest importance in meteorology. The second is a valuable method for measuring attainable heights, and is intimately connected with the problem as to the relation between the pressure and density of the air. Thus it would be possible, by barometric observations at a series of points in the same vertical line, to obtain a knowledge of this relation—more and more truly approximate the closer and more numerous the points of observation taken. At best, however, such a method could give the law connecting density with pressure for those pressures only which are less than the normal atmospheric pressure. The problem is better solved otherwise.

Assuming Boyle's law that *the density of air is directly as the pressure*, we can now integrate the equation of equilibrium

$$\delta p = -\rho \delta V,$$

and put it in the form

$$p = p_0 e^{-\gamma V},$$

where  $p_0$  is the pressure at zero potential and  $K$  is the constant ratio of the pressure to the density.

For all attainable heights in our atmosphere we may assume the force of gravity to be the same. Hence we may write  $V = gh$ ,

where  $g$  is the force acting on unit mass at height  $h$ . If we put  $K = gH$ , the equation becomes

$$p = p_0 e^{-h/H},$$

where  $H$  is obviously the height of a fluid of uniform density  $p_0/K$  which would give at its base the pressure  $p_0$ —in other words, the height of the homogeneous atmosphere, as it is called. Its value is readily found, since it bears to the height of the mercurial barometric column the same ratio which the density of mercury bears to the density of the atmosphere at the sea-level. For dry air at  $0^\circ \text{C}$ . and with  $g$  taken as equal to 981 dynes ( $= 32.2$  poundals nearly), the value of  $H$  is  $7.9887 \times 10^5$  centimetres, or 26,210 feet. Hence the formula giving the height above the sea-level in terms of the pressure may be written

$$h = 7.9887 \times 10^5 \times \text{Nap. log. } (p_0/p).$$

In practice this formula must be modified to suit regions where  $g$  is other than 981, and where the temperature is other than  $0^\circ$ . The effect of the water-vapour present must also be taken into account, and the constants involved carefully tested by observation. The subject is treated in detail under BAROMETER.

Boyle's  
experiment.

In an appendix to the *New Experiments, Physico-Mechanical, &c., touching the Spring of Air* (1660), Robert Boyle states that the density of air is directly as the pressure. His apparatus and method of experiment are as follows. A U-shaped tube is taken, one of whose limbs is considerably longer than the other. The shorter limb is closed at the end; and the whole apparatus is set vertically with the open end pointing upwards. A small quantity of mercury fills the bend, so that at the beginning of the experiment the two mercury surfaces are at the same level. Hence the air confined in the shorter limb is subjected to a pressure along its lower surface equal to the atmospheric pressure, or one atmosphere as it is commonly called. As the height of the air column in the closed tube is small, the pressure and density are practically the same throughout. Now let mercury be poured into the longer limb. The free mercury surface will be observed to rise in the shorter limb, so that the air confined there becomes compressed into smaller bulk. Since the mass of air has not altered, the density is obviously inversely as the bulk, and can therefore be easily measured. Again, the pressure to which the confined air is now subjected is equal to the pressure over that surface in the mercury in the open limb which is at the same level as the free mercury surface in the closed limb. But this pressure is clearly the sum of the atmospheric pressure and the pressure due to the superincumbent column of mercury, which latter can be readily expressed in atmospheres if the height of the barometer is known. In other words, divide the vertical distance between the two mercury surfaces by the height of the barometer column. The quotient added to unity gives the required pressure in atmospheres.

Mariotte's  
experiments.

Fourteen years after the date of the publication of Boyle's results, Mariotte,<sup>1</sup> working independently, discovered the same law, which is still widely known on the Continent as Mariotte's law. He supplemented Boyle's experiments by investigating the effect of pressures less than that of the atmosphere, and proved that the same law held at these diminished pressures. His method was essentially as follows. A barometer tube is filled in the ordinary way with mercury and fixed up as in the Torricellian experiment. A little air is then introduced at the lower end of the tube which is dipping in the reservoir of mercury. This air travels up the tube and fills the Torricellian vacuum at the top, thereby depressing to a slight extent the barometer column. The amount of depression divided by the true height of the barometer gives the pressure in atmospheres which acts upon the air in the tube. The tube, always kept truly vertical, dips in a reservoir of mercury sufficiently deep to admit of its complete immersion. For a certain position of the tube the free surfaces of mercury in the tube and reservoir are

at the same level. For that position the confined air is at the atmospheric pressure; and for any higher position of the tube the pressure in the confined mass of air is less than the atmospheric pressure by the pressure due to the column of mercury between the free surfaces. Recent experiments by Kraevitch and Petersen (*Journal of the Russian Chemical Society*, vol. xvi.) seem to show that very rarefied air is very far from obeying Boyle's law. At such low pressure, the condensation of the gas upon solid surfaces is an important factor.

For most ordinary purposes Boyle's law—that, at constant temperature, the density of a gas varies directly as the pressure—may be assumed to be true, at least for moderate ranges of pressure; but the careful investigations of later experimenters, such as Oersted, Despretz, Dulong, Regnault, Andrews, Cailletet, and Amagat, have proved that the law is only approximate for every known gas, and that the deviation from correspondence with the law is different for each gas. The most recent investigations are those of Cailletet and Amagat, who have carried the results to much higher pressures than former experimenters employed. Both adopted in the first place a form of apparatus essentially the same as Boyle's, only much longer. The gas was subjected to the pressure of a mercury column enclosed in a strong narrow steel tube; and, as oxygen acts vigorously upon mercury at high pressures, nitrogen was used. In this way Cailletet<sup>2</sup> attained to a pressure of 182 metres of mercury, and Amagat<sup>3</sup> to a pressure of nearly 330.

Having thus determined accurately the corresponding pressures and densities of nitrogen, Amagat proceeded to determine the relation for other gases by Pouillet's differential method. That is, the pressure to which the new gas was subjected was made to act simultaneously upon a given mass of nitrogen, whose volume could be readily measured and pressure estimated. Oxygen, hydrogen, carbonic oxide, dry air, olefiant gas, and marsh gas were investigated in this way. The general results obtained by Amagat are exhibited in the subjoined chart taken from his paper. For all gases except hydrogen the product  $pV$  (pressure into volume), instead of being constant, as Boyle's law would require, diminishes at first as the pressure is increased. At a certain pressure, however, different for each gas, the diminution ceases, and if the pressure is still further increased the product  $pV$  begins to increase also, and continues so to do to the greatest pressure used. In the case of hydrogen the product increases from the very beginning.

On the diagram, abscissæ represent pressures in metres of mercury, and the ordinates represent the deviations from the Boylean law. It will be observed that all the curves pass through the point on the pressure axis which represents a pressure of 2.4 metres of mercury. If  $\pi$  represents the product  $pV$  for any gas at this pressure, and  $\pi'$  the corresponding product for any other pressure, then we may write

$$\pi/\pi' = 1 + \delta,$$

where  $\delta$  represents the deviation from Boyle's law. All the curves except that for hydrogen show a well-marked minimum, at and near the pressure corresponding to which the particular gas obeys Boyle's law. For the several gases these positions occur at the pressures as given in the following table:—

Nitrogen .....	50 m.	Carbonic acid .....	50 m.
Oxygen .....	100 m.	Marsh gas .....	120 m.
Air .....	65 m.	Olefiant gas .....	65 m.

For olefiant gas  $\delta$  is so great, and varies so rapidly, that only portions of the curve are represented. The value of  $\delta$  for its minimum point is  $-1.3$ , while the corresponding value for oxygen is  $-0.05$ . In these experiments the temperature of the gases varied between  $18^\circ$  and  $22^\circ \text{C}$ .

Amagat<sup>4</sup> has extended his researches to higher temperatures up

<sup>1</sup> *Traité de la Nature de l'Air*, 1676.

<sup>2</sup> *Journal de Physique*, vol. viii., 1879.

<sup>3</sup> *Annales de Chimie et de Physique*, vol. xix., 1880.

<sup>4</sup> *Annales de Chimie et de Physique*, vol. xxii., 1881.

to 100° C. The general characters of the curves obtained for hydrogen, nitrogen, olefiant gas, and marsh gas remain the same as at the ordinary temperature; that is, with the exception of hydrogen, the product  $pv$  decreases to a minimum and then increases indefinitely.

The position of the minimum changes with the temperature. Thus for olefiant gas and carbonic acid gas (whose properties were also studied at these higher temperatures), the pressure at which the minimum occurs increases with the temperature, while in the case of nitrogen and marsh gas this critical pressure decreases as the temperature rises. Probably at some temperature higher than 160° olefiant gas and carbonic acid gas would begin to behave like nitrogen, and all would appear to tend more and more, as the temperature rises, to the condition of which hydrogen is the type. That is, the deviation from the Boylean law up to the minimum point would steadily decrease until finally the curve would cease to

have a marked minimum. Their results were published in 1801<sup>1</sup> and 1802<sup>2</sup> respectively; and it is upon the authority of the latter, who accidentally became acquainted with the fact, that the law is now named after Charles. The careful measurements of Magnus,<sup>3</sup> Regnault,<sup>4</sup> Jolly, and others have established that there is an appreciable difference in the coefficients of expansion for the different gases. The difference is slight for the so-called permanent gases—air, nitrogen, oxygen, hydrogen, and marsh gas; but for the more easily liquefiable gases it is quite marked. The mean coefficient of expansion for air between 0° C. and 100° C. and at the ordinary atmospheric pressure is .003665 per degree, and the value for any one of the gases just mentioned does not certainly differ from this by one-half per cent.<sup>5</sup> This may be expressed by the formula

$$v = KT,$$

where  $K$  is a constant and  $T$  the temperature measured from absolute zero, which is 274° C. below the freezing point of water (see HEAT). When  $T$  is constant, we have by Boyle's law the product  $pv$  also constant. Hence we may combine the two laws in the form

$$pv = RT,$$

where  $R$  is a constant. We thus see that, Boyle's law being assumed to be true at all temperatures, Charles's law, if true for any given pressure, is true for every other pressure. Further, if  $v$  is kept constant the rate of increase of  $\log p$  with temperature will be expressed by the same number as the rate of increase of  $\log v$  when  $p$  is kept constant. Experiment has fully verified this conclusion to as close an approximation as Boyle's and Charles's laws themselves are fulfilled. The rate of increase of  $\log v$  with temperature, or, what is the same thing, the ratio of the rate of increase of the volume to the original volume, is given by the formula

$$\frac{1}{v} \frac{dv}{dT} = \frac{1}{T};$$

and this is the measure of the coefficient of expansion at temperature  $T$ . Hence the coefficient of expansion diminishes as the temperature rises, a conclusion also in accordance with experiment so long as we are dealing with gases which nearly obey Boyle's and Charles's laws.

We have seen, however, that even in the case of Amagat's hydrogen the departure from Boyle's law is very marked at the higher pressures; and therefore we cannot expect a closely numerical agreement between the results of experiment and the results of calculation from the above formula. Thus, it is not surprising that practically the coefficient of expansion should be affected by the pressure, as Amagat's experiments clearly show,—although in the equation deduced above the pressure does not enter. In the following table given by Amagat, the second column contains the mean coefficients of expansion of hydrogen between 17° and 60° C. at the pressures given in the first

have a marked minimum. For any one gas, the higher the temperature the less the curvature at the minimum point; and the comparison of different gases seems to indicate that the curvature is greater for the more easily liquefiable gas. At sufficiently high temperatures the law of compressibility for all gases approximates to the relation

$$P(V - a) = \text{constant},$$

where  $P$  is the pressure,  $V$  the volume, and  $a$  a constant. Hydrogen follows this law very closely at the ordinary temperature of the air, as the straightness of its representative curve shows at a glance.

Charles's law. Amagat has further discussed by means of his results the law of dilatation of gases. This law is named Charles's law, after the discoverer of it. Stated simply, it is that at constant pressure every gas expands by the same fraction of itself for a given rise from a given temperature. Charles did not publish his results; and it was not till fifteen years later, when Dalton and Gay-Lussac, working independently, rediscovered it, that the law became generally known.

<sup>5</sup> The first who really gave accurate values of these quantities was Rudberg.

column; and the third column contains the corresponding mean coefficients between 60° and 100° C.

Pressure in Metres of Mercury.	17°-60°.	60°-100°.
40	·0033	·0029
100	·0033	·0028
180	·0031	·0027
280	·0030	·0025
320	·0028	·0024

The temperature effect upon the coefficient of expansion, as shown by these numbers, is approximately that indicated above, viz., that at constant pressure the coefficient of expansion is inversely as the absolute temperature. A glance down each column shows at once the marked effect of pressure. In this steady decrease of the coefficient of expansion with increase of pressure, hydrogen stands alone amongst the substances discussed by Amagat. His conclusions are given in these words:—

1. The coefficient of expansion of gases increases with the pressure to a maximum, after which it decreases indefinitely.
2. This maximum occurs at the pressure for which at constant temperature the product  $p\nu$  is a minimum, that is, the pressure at which the gas follows for the instant Boyle's law.
3. With increasing temperature this maximum becomes less and less sensible, finally disappearing with the minimum characteristic of the compressibility curve.

Thus, as hydrogen does not show this minimum characteristic, its coefficient of expansion has no maximum value. Possibly at lower temperatures hydrogen may, however, possess these characteristics.

It thus appears that the simple gaseous laws established by Boyle and Charles are most nearly fulfilled by those gases which are difficult to liquefy, and are better fulfilled by all the higher the temperature is. When a gas is near its point of liquefaction the density increases more rapidly than the pressure, or in other words the volume diminishes more quickly than Boyle's law requires. When the point of liquefaction is actually reached, the slightest increase of pressure condenses the whole of the gas into a liquid; and in this state the alteration of volume is very small even for a large increase of pressure.

Iso-  
therms.

The transition from the gaseous to the liquid state is conveniently studied by the help of isothermal lines, which may be generally defined as curves showing the relation between two mutually dependent variables for given constant temperatures. Such variables are the pressure and volume of a mass of gas. Let the numbers representing the volumes be measured from a chosen origin along a horizontal axis, and the numbers representing the pressures similarly along a vertical axis passing through the same origin. If we consider a mass of gas at a given temperature, for any volume that can be named there will be a definite pressure corresponding, and *vice versa*. Hence the point whose coordinates are the corresponding volume and pressure is completely determined if either coordinate is given. The temperature always being kept constant, let now the volume change continuously. The pressure will also alter according to a definite law; and the point whose coordinates are at any instant the corresponding volume and pressure will trace out a curve. This curve is an isothermal curve, or simply an *isotherm*. If Boyle's law were fulfilled, the equation to the isotherm for any given temperature would be of the form

$$p\nu = \text{constant.}$$

The isotherm would be a rectangular hyperbola, whose asymptotes are the coordinate axes. For any gas not near its point of liquefaction the isotherm will not deviate greatly from the hyperbolic form.

Let now the pressure be kept constant, and the gas raised

somewhat in temperature. The volume of course increases, and the corresponding point on the diagram moves off the original isotherm. Through this point in its new position we can draw a second isotherm corresponding to the new temperature. And thus the whole field may be mapped out by a series of isotherms, each one of which corresponds to a definite temperature. The higher the temperature the farther does the isotherm lie from the origin. Such a mapped out diagram or chart shows at a glance the relations between the volume, pressure, and temperature of a given mass of gas, so that if any two of these are given the third can be found at once.

So long as the substance is in the gaseous form, the isotherm remains approximately hyperbolic; but at the pressure at which liquefaction takes place a marked change occurs in the form of the curve. For greater definiteness consider the case of a gramme of steam at 100° C. and at a pressure somewhat below one atmosphere. As the pressure is increased, the volume diminishes appreciably faster than Boyle's law requires, but still in such a way as to give an approximately hyperbolic form to the isotherm. When the pressure reaches one atmosphere, however, any further increase is accompanied by the liquefaction of the whole; that is, the volume suddenly diminishes from 1647·5 cubic centimetres to 1 cubic centimetre. Between these extremes of volume, the isotherm is a straight line parallel to the horizontal axis. The pressure remains constant until the whole of the gas is liquefied. In other words, *the pressure of a gas in presence of its liquid does not alter provided the temperature is kept constant*. This is a partial statement of the more general law that the temperature of the liquid surface alone determines the maximum pressure which its vapour or gas in contact therewith can exert (see HEAT). After the whole has been liquefied, any increase of pressure is accompanied by a very minute diminution of volume. Hence the isotherm rises abruptly from the point whose coordinates are 1 cubic centimetre and 1 atmosphere, becoming nearly but not quite vertical. Thus, the isotherm for water-substance at 100° consists of three parts:—an approximately hyperbolic portion for pressures less than one atmosphere, the substance being then wholly gaseous; a horizontal portion, corresponding to the state in which the substance is partly liquid partly gaseous; and a nearly vertical portion for pressures higher than one atmosphere, the substance being then wholly liquid. If we trace out the isotherm for some higher temperature, say 150° C., we obtain the same general characteristics. The straight line portion, however, is not so long, for two reasons:—the steam must be reduced to a smaller volume before liquefaction begins; and the volume of the liquid when condensed is greater. The pressure corresponding to the transition state is in this case 4·7 atmospheres, and the range of volumes is from 384·4 cubic centimetres in the gaseous state to 1·038 cubic centimetres in the liquid state. It thus appears that the positions of the two points of abrupt change on an isotherm draw nearer the higher the temperature, coming together finally when the temperature has reached a certain critical value. In other words, at and above a certain temperature a liquid and its vapour cannot co-exist. This temperature for water-substance is very high, somewhere about the point of fusion of zinc, and is therefore difficult to measure. Dr Andrews, however, in his classical researches on carbonic acid gas,<sup>1</sup> to which we owe most of what is said above, has discussed the whole subject in a very complete manner. This substance, at a temperature of 13°·1 C., begins to liquefy at a pressure of 47 atmospheres. During the process of liquefaction there is a perfectly visible

Andrew's  
results  
for car-  
bonic acid  
gas.

<sup>1</sup> Phil. Trans., 1869.

liquid surface separating the two coexisting states of the substance; and the isotherm has a corresponding straight line portion. At a temperature of  $21^{\circ}5$  C. liquefaction occurs at a pressure of 60 atmospheres. The horizontal portion of the isotherm, which marks the co-existence of the gaseous and liquid states, is considerably shorter than at the former temperature. The isotherm for  $31^{\circ}1$  C., however, has no such rectilinear characteristic; and at this and higher temperatures the substance is never during the whole compression in two distinct conditions at once. It is impossible to say when the dense gaseous condition passes into the light liquid condition. The two states are absolutely continuous. The critical temperature—that is, the temperature below which there is a distinct separation between the liquid and the gas—is fixed by Dr Andrews at  $30^{\circ}92$  C. for carbonic acid gas. Above this temperature it is impossible to obtain a free liquid surface in a closed vessel. This conclusion had already been arrived at by Faraday in 1826, when he considered himself entitled to state that above a certain temperature no amount of pressure will produce the phenomenon known as condensation.

Cagniard-Latour's experiments.

Andrews's results also give the true explanation of the observations made by Cagniard-Latour<sup>1</sup> in 1822 upon the effect of high temperature on liquids enclosed in glass tubes which they nearly filled. He found that at a certain temperature the free liquid surface disappeared, and the tube became filled with a substance of perfectly uniform appearance throughout. He concluded that the whole had become gaseous. In reality he had reached the critical temperature at which the liquid and gaseous conditions pass continuously the one into the other. The following are Cagniard-Latour's estimated values for the temperature and pressure of various substances at the critical point

	Temperature.	Pressure.
Ether.....	$175^{\circ}$ C.	33 atmospheres.
Alcohol .....	$215^{\circ}$ "	112 "
Bisulphide of carbon.....	$255^{\circ}$ "	71 "

Avenarius<sup>2</sup> and Drion<sup>3</sup> have studied the critical temperatures of other substances, such as sulphuric acid, acetone, and carbon tetrachloride. The substances, however, which can be so studied are comparatively few, since the greater number of those which are liquid under ordinary conditions have their critical temperatures very high, while the majority of those which are gaseous have theirs very low.

The liquefaction of gases.

The necessity for a very low temperature long prevented the obtaining in a liquid form of the standard gases—hydrogen, oxygen, nitrogen, &c.—which were accordingly distinguished by the name *permanent gases*. Faraday<sup>4</sup> proved that these could not be liquefied at a temperature of  $-110^{\circ}$  C., even when subjected to a pressure of 27 atmospheres. Natterer<sup>5</sup> likewise failed to reduce these gases to the liquid state, even at a pressure of 3000 atmospheres. His means for reducing the temperature were not satisfactory. In 1877 Cailletet and Pictet, working independently, first successfully effected their approximate liquefaction. The former compressed each of the gases oxygen, nitrogen, and carbonic oxide to 300 atmospheres in a glass tube, which was cooled to  $-29^{\circ}$  C.<sup>6</sup> When the gas was allowed to escape, it did so in the form of a cloud,

condensing for the moment to the liquid state under the influence of the extreme cold produced by the rapid expansion of the gas. Pictet in a similar way obtained an issuing stream of liquid oxygen. Von Wroblewski and Olzewski<sup>7</sup> have more recently obtained oxygen, nitrogen, and carbonic oxide in a more evident liquid state. They used Cailletet's form of apparatus, and cooled the gas by means of the evaporation of liquid ethylene. Under this extreme cold they observed these substances forming a well-defined liquid in the bottom of the tube. The following table gives the results of five different observations at slightly different temperatures.

Temperature, C...	$-129^{\circ}6$	$-131^{\circ}6$	$-133^{\circ}4$	$-134^{\circ}8$	$-135^{\circ}8$
Pressure, in atmos.	27.02	25.85	24.4	23.18	22.2

At slightly higher temperatures, the pressure necessary for the liquefaction increased very rapidly. Nitrogen and carbonic oxide were not so easily reduced, remaining still gaseous at  $-136^{\circ}$  C., and under a pressure of 150 atmospheres. By a sudden diminution of the pressure to 50 atmospheres there was obtained under the influence of the reduced temperature a rapidly evaporating liquid. The critical point of oxygen has been experimentally fixed by Von Wroblewski<sup>8</sup> at  $-113^{\circ}$  C. and 50 atmospheres pressure. With the data given by Amagat's researches, Sarrau<sup>9</sup> has calculated from a formula of Clausius's the following values of the critical temperature and pressure for oxygen, nitrogen, hydrogen.

	Critical Temperature.	Critical Pressure.
Oxygen.....	$-105^{\circ}4$ C.	48.7 atmospheres.
Nitrogen.....	$-123^{\circ}8$	42.1 "
Hydrogen.....	$-174^{\circ}2$	98.9 "

It will be observed that Von Wroblewski's observed values for oxygen are in remarkably close agreement with the calculated values given here. Apparently oxygen is just at the limit fixed by Faraday.

The behaviour of a gas under varying pressure is a Manometer phenomenon of great practical importance, and gives a valuable method for measuring pressures (see MANOMETER).

A modification of the ordinary mercury manometer is used for measuring volumes, and is especially valuable in estimating the densities of substances which cannot be put into water, such for example as liquids or powders. The closed end of the manometer tube, which by means of a stop-cock may be opened to the air at will, is fitted to a flask with which it may be put into connexion when required. Two fiducial marks are then made upon it—one at the position where the mercury surfaces in the two limbs of the tube are co-level, and the other somewhat higher at a convenient spot. Between the two marks the tube expands into a bulb, thereby increasing the intervening volume and minimizing the effect of any slight error in bringing the mercury surface to the higher mark. Let the volume of the flask and tube down to the higher mark be  $v$ , and the volume of the rest of the tube down to the lower mark  $V$ . At first the volume of air in the flask and tube is  $V + v$ , at the atmospheric pressure  $P$ . Now pour mercury into the open end till the liquid surface in the closed end reaches the higher mark. The air has been compressed to volume  $v$ ; and the corresponding pressure, as measured by the balanced mercury column, is  $p + P$ . Hence

$$(p + P)v = P(V + v).$$

Let now a volume  $x$  be placed in the flask, and let the

same succession of operations be made. Then, if  $p'$  be the increase of pressure necessary to bring the mercury surface from the lower to the higher fiducial mark, we have

$$(p' + P)(v - x) = P(V + v - x).$$

As  $V$  can be readily determined by gauging the tube, and as  $P, p, p'$  are all known, the quantities  $v$  and  $x$  can be at once found from these equations.

Air-pumps.

In many experiments on the properties of gases it is necessary to have an efficient and rapid means for altering the density. Instruments for this purpose are called air-pumps, and their function may be either to rarefy or condense the air—usually the former.

Invented by Von Guericke.

Otto Von Guericke of Magdeburg constructed the first air-pump about the year 1652. It was simply a spherical glass vessel opening below by means of a stop-cock and narrow nozzle into the cylinder of an "exhausting syringe," which inclined upwards from the extremity of the nozzle. The cylinder, in which a well-fitting piston worked, was provided at its lower end with two valves. One of these opened from the nozzle into the cylinder, the other from the cylinder into the outside air. During the down-stroke of the piston the former was pressed home, so that no air entered the nozzle and vessel, while the latter was forced open by the air which so escaped from the cylinder. During the return-stroke the latter was kept closed in virtue of the partial vacuum formed within the cylinder, while at the same time the former was forced open by the pressure of the denser air in the vessel and nozzle. Thus, at every complete stroke of the piston, the air in the vessel or receiver was diminished by that fraction of itself which is expressed by the ratio of the volume of the available cylindrical space above the outward opening valve to the whole volume of receiver, nozzle, and cylinder.

Improvements by Boyle, Hooke, Papin, &c.

Boyle, on hearing of Von Guericke's success in applying the expansive properties of air as a means to its rarefaction, constructed a machine essentially the same as Von Guericke's, of which no description had then been published. Boyle, however, made the exhausting cylinder a continuation of the nozzle, which was thus considerably reduced in size, and worked the piston by means of a wheel and ratchet work. He also employed a transparent glass receiver with removable cover, so that the operator could observe what was going on inside, and more easily alter the contents. Other modifications and improvements followed rapidly; and in the carrying out of these Boyle was greatly aided by Hooke, who conceived the happy idea of using two syringes opening into the same duct from the receiver. This improvement has recently been credited to Papin.<sup>1</sup> In this form the pistons are worked by the same toothed wheel, and are so adjusted that the one rises as the other falls. This arrangement not only doubles the rate of exhaustion per stroke, but vastly increases the ease of working. In the single-barrelled form the piston is drawn back against a pressure of air which is greater the more complete the exhaustion is within; but in the double-barrelled form the downward pressures upon the two pistons to a certain extent counteract each other, producing opposite rotational effects on the toothed wheel and driving handle. Boyle also early adopted the flat plate, on which could be set receivers of various shapes and sizes. The junction of the plate and receiver he made tolerably air-tight by covering the plate with wet leather and having the receiver rim ground flat. According to Gerland, the invention of the plate is due to Huygens, who constructed the first air-pump so provided in 1661, shortly after a visit to London, where his interest in the subject was awakened by Boyle. To Huygens, probably in conjunction with Papin, is also due the applica-

tion of the mercury manometer to measure the pressure in the receiver—an indispensable equipment in all serviceable air-pumps. The form of the piston plugs and valves received the special attention of Papin, who by his refined and detailed improvements did much to increase the efficiency of the apparatus.

The important characteristics of an efficient air-pump are as follows. The piston must work smoothly and easily. The valves must act precisely, and be when closed absolutely air-tight. The plate on which the receivers rest must be smooth and plane, so that the ground edges of the receivers may be in close contact all round. This perfect fitting is beyond the powers of the best workmanship, so that it is necessary to press between the receiver and plate a thin layer of lard, which renders the junction air-tight. Somewhere in the duct leading from the receiver to the piston cylinders, a stop-cock must be fixed, so that it may be possible to shut off the receiver completely from these. Then a second stop-cock is required as a ready means for admitting air to the receiver, whenever the need should arise. A combination three-way stop-cock is a very usual form. And, finally, the apparatus should be provided with a pressure gauge—a mercury manometer communicating by means of a duct with the main duct and receiver.

The double-barrelled form of reciprocating air-pump, as Bianchi's finally employed by Boyle, is still much in use; but it is gradually being superseded by Bianchi's, which has but one cylinder and piston. The piston is, however, double-acting, as the cylinder communicates both above and below by suitable valves with the main duct which leads to the receiver. Hence, during both the up and down strokes of the piston, exhaustion is being effected, the gas which is in the *diminishing* chamber being driven out through a suitable valve to the open air. The chief merit of Bianchi's machine, however, as compared with the older form, lies in the mechanism by which the piston is driven. The end of the piston rod is attached by a crank to a rotating horizontal axle, which is in gearing with the axle of a fly-wheel. The piston cylinder is capable of a reciprocating oscillatory motion about its lower end, which pivots on a horizontal axis. Thus, as the crank rotates, the piston rises and falls in the cylinder, and oscillates along with it from side to side. The driving power is applied to a handle fixed to the fly-wheel. This substitution of a continuous rotatory motion for a reciprocating motion greatly facilitates rapid exhaustion.

At every complete stroke of the piston the pressure of air in the receiver is reduced by a definite fraction of itself, which depends upon the relative volumes of the receiver and piston cylinder. Hence the absolute change of pressure per stroke is smaller as the pressure is smaller; and the rate of exhaustion at very low pressures becomes practically inappreciable. There is, in fact, a practical limit to exhaustion, the particular value of which depends upon the special characteristics of the instrument. The best air-pumps of the type described above cannot reduce the pressure to less than what would balance one or two millimetres of mercury—that is, to what is technically called a pressure of one or two millimetres. To obtain a lower pressure or a *higher vacuum*, as it is commonly termed, requires the use of a different principle.

In a well-constructed barometer the region above the mercury contains no air. It is not an absolute vacuum, but is filled with vapour of mercury at a very low pressure—according to Regnault, .0372 mm. at 20° C., and .02 mm. at 0° C. The way in which the Torricellian vacuum has been applied to give a practical air-pump has been described in MERCURIAL AIR-PUMP. So long as mercury vapour is permitted to pass freely through the exhausting tubes, it is impossible to obtain by the mercurial air-pump

<sup>1</sup> See Gerland, in *Wiedemann's Annalen*, 1877, 1883.

pressures lower than the fortieth of a millimetre. If, however, there is placed somewhere in the duct leading from the mercury pump to the receiver a non-volatile substance which absorbs mercury vapour, the mercury vapour will be arrested. With similar precautions for the absorption of water vapour or other vapour which may be present, it is possible to obtain very low pressures indeed. Thus Crookes<sup>1</sup> in his radiometer experiments obtained pressures as low as  $\cdot 00015$  mm. or the  $\cdot 2$  millionth of an atmosphere. The form of pump used was of Geissler's type. The water vapour was absorbed by phosphoric anhydride. Sulphur was used to absorb the mercury vapour; and on the further side metallic copper was placed to absorb any sulphur vapour which might tend to pass.

**Test of a good vacuum.** The best test of a good vacuum is the electrical test. Disruptive discharge through a long tube filled with gas is possible only when the gas is very rare, but there is a point in the rarefaction of a gas at which the discharge passes most easily. In other words, the dielectric strength of a gas reaches a minimum as its pressure is diminished, and it is possible to obtain such a high vacuum that electric discharge will not take place through any considerable length of the exhausted space (see *ELECTRICITY*). In this connexion we may notice a simple but instructive experiment of Dewar's. He carefully exhausted a vacuum tube, in which he had previously inserted a piece of carbon. In the last stages of the exhaustion the carbon was strongly heated so as to drive off most of the gas which is always condensed on its surface. After the completion of the exhaustion, the tube was sealed up and the carbon allowed to cool. As it cooled, it condensed over its surface the greater portion of the small quantity of gas left in the vacuum tube. The vacuum was thus vastly improved, so that it was impossible to pass an electric spark between two platinum electrodes which had been previously fused into the glass. A gentle heat applied to the carbon, however, was sufficient to drive off from its surface enough of the occluded gas to raise the pressure to the point necessary for the passage of the electricity. As the carbon cooled again, the high vacuum was restored and the discharge ceased.

**Condensing air-pumps.** It is hardly necessary to do more than mention the other class of air-pumps. Let the essential valves in an exhausting pump have their actions reversed, and the apparatus will become a condensing pump. The condensing syringe is the usual form of such a pump; but, compared to the exhausting instrument, it has very limited applications. For the mere obtaining of high pressures hydraulic means are preferable, being at once more manageable and less dangerous. Besides, even moderately slow compression of a gas is accompanied by considerable rise of temperature, just as rarefaction of a gas is accompanied by appreciable lowering of temperature. In the former case work is done in compressing the gas against its own pressure, and this energy appears as heat which raises the temperature of the gas. In the latter case the gas in expanding draws upon its own energy and so cools.

**Thermal properties, kinetic theory, &c.** The thermal properties of gases are treated as a branch of mathematical physics under *HEAT* and *THERMODYNAMICS*, where also will be found discussed such experimental details as bear intimately upon the theory. The article *ATOM* contains a concise statement of the modern kinetic theory of gases; and in *CONSTITUTION OF BODIES* and *DIFFUSION* certain more special aspects of the same theory are regarded. For the mathematical theory see *MOLECULE*. The principles embodied in these articles have been assumed throughout the present article.

**Aitken's experiments.** The cooling of a gas by its own expansion may be observed in one of its effects during exhaustion in an ordinary receiver. Frequently a cloud of minute drops of water—a veritable fog—forms in the exhausted air. The reason simply is that the air has become cooled below its dew-point, or the temperature corresponding to the pressure of water vapour present. If the receiver is first filled with dry air and then exhausted, no cloud forms. Also if the air is carefully filtered through cotton wool, no cloud

forms, even though the air be thoroughly saturated with water vapour. This latter fact was established by Mr Aitken in his beautiful series of experiments on dust, fogs, and clouds.<sup>2</sup> It thus appears that the formation of fog and cloud depends not only upon the humidity of the air but also upon the amount of dust in the air. The little particles of dust are necessary as nuclei upon which the vapour can begin to condense. The more numerous the dust particles the finer are the drops which form on them. As these coalesce into larger drops and fall, they bring down the dust nuclei with them; and hence the tendency of rain is to clear the atmosphere, and make conditions less favourable for the formation of more cloud and rain. Thus rain, fog, and dew all require for their formation a free solid surface, colder than the temperature of saturation, on which to condense. In a dustless atmosphere no cloud can ever form.

It has been already pointed out that when a fluid is in motion it can no longer be regarded as even approximately possessing the properties of the ideal perfect fluid. The postulate that the stress between contiguous portions is perpendicular to the common interface cannot be for a moment admitted. A few examples will make this clear. Thus, if a vessel filled with a liquid be set in rotation, the liquid will soon be found to be rotating with the vessel; and if the motion of the vessel be stopped, the motion of the liquid inside will gradually subside. These phenomena show the existence of a stress tangential to the fluid elements, whereby the relative motion of the different parts of the system is gradually destroyed, until the vessel and its contents behave as one solid body. Again, a fluid stream flowing along a tube or canal moves fastest in the middle, slowest at the bounding walls, and with all possible intermediate speeds at intermediate places. This retardation, due in the first instance to the action of the walls upon the fluid in direct contact therewith, and then to the friction between the successive contiguous sheets of fluid, plainly implies the existence of tangential stress. The action of the wind in causing waves on the smooth surface of a sheet of water is a further illustration.

In the discussion of fluid motion, however, it is customary to consider first the properties of the ideal fluid in this respect. Under *HYDROMECHANICS*, and especially under *ATOM*, will be found the mathematical theory treated in full so far as the motion of a non-viscous fluid is concerned.

The possibility of setting up vortex-motion in a fluid depends upon its imperfection, upon the property of viscosity or fluid effects of friction which is possessed by all known fluids. Some of the more obvious effects of this property have been already noticed. Its effects indeed are conspicuous wherever there is relative motion of the contiguous parts of a fluid. A current of air moving through a mass of air at rest soon loses its momentum; a solid body moving through still air likewise has its motion retarded. The loss of energy which a meteoric stone so suffers as it speeds through the atmosphere appears in the form of heat, which is sufficient to make the stone glow to incandescence or to the temperature of rapid combustion. The waves of rarefaction and condensation, which constitute sound physically, gradually decay in virtue of viscosity. It appears that the rate of this decay is quickest for the shortest waves; so that a sound after travelling through a long distance may lose its shriller constituents and so be modified and mellowed. It is viscosity also which supports the minute dust particles and cloud-forming drops of water in our atmosphere. These are bulk for bulk heavier than the atmosphere, and in tranquil air are slowly sinking. The slowness of their downward motion is directly due to the effect of fluid-friction.

The term fluid-friction is applied because of the similarity of its effects to the effects of friction between solid masses. Other-friction wise there need be no further resemblance. The true nature of dependence of friction between solid surfaces is not known; possibly, as suggested on diffu- by Sir W. Thomson, it may be in great measure electrical. In the case of gases, however, the origin of friction is more apparent. Its laws can be deduced from the kinetic theory, and depend directly upon the principle of diffusion. According to the kinetic theory of gases, the molecules of a gas are in constant motion amongst themselves. Compared to their own dimensions, they are by no means closely packed, so that any individual molecule travels a comparatively large space between its encounters with other molecules. Any two contiguous regions are continually interchanging molecules. This diffusion of a gas into itself we have no means of measuring experimentally, as we cannot deal with individual molecules. Suppose, however, that we have two contiguous layers of a gas flowing in parallel directions with different speeds. The general drift of molecules in the one layer is faster

<sup>1</sup> See his Bakerian Lecture, *Phil. Trans.*, 1878, clxix. 300.

<sup>2</sup> *Trans. Roy. Soc. Edin.*, 1880-81.

than in the ether. But this difference will not prevent the individual molecules diffusing across the interface between the layers. Diffusion will go on freely. The result will be that the slower moving layer will on the whole gain momentum in the direction of its motion and the faster moving layer lose momentum. Thus, diffusion tends to the equalization of momentum between two contiguous regions, and the rate at which this takes place across unit area is the measure of the viscosity. Maxwell has proved<sup>1</sup> that the viscosity so measured is independent of the density of the gas when the temperature is constant; whereas the relation between the viscosity and temperature depends upon the particular mode of action between the molecules when they approach each other.

The above definition of viscosity is not one which can be used in experimental determinations, since we cannot take account of the individual molecules of a gas. The coefficient of viscosity must be defined in terms of directly measurable quantities.

**Viscosity defined physically.** Maxwell has defined viscosity in these words:—the viscosity of a substance is measured by the tangential force on unit of area of either of two horizontal planes at the unit of distance apart, one of which is fixed, while the other moves with unit of velocity, the space between being filled with the viscous substance. This is the dynamical definition. When the effects of viscosity on the internal motions of a fluid itself are being considered it is often more convenient to use the kinematical definition. It is given in terms of  $\mu$ , the coefficient of viscosity, by the equation

$$\mu = \rho \nu,$$

where  $\rho$  is the density of the substance, and  $\nu$  the kinematic viscosity.

**Experiments on viscosity.** The viscosity of fluids has been determined experimentally in three distinct ways—by flow of the fluid through tubes, by motion in the fluid of pendulums or vibrating disks, and by the oscillations of spheres filled with the fluid. The last was employed by Helmholtz and Von Piotrowski in their investigation of liquids,<sup>2</sup> but it is not applicable to the case of gases. Experiments on the flow through capillary tubes have been carried out by Poiseuille<sup>3</sup> for liquids, and by Graham,<sup>4</sup> Meyer,<sup>5</sup> Springmühl,<sup>6</sup> and Puluj<sup>7</sup> for gases. This, the transpiration method, is the most effective for comparing viscosities, which are directly proportional to the times of transpiration of the respective gases. There is, however, a little uncertainty as to the effect of the capillary tube,—so that, for measuring absolutely the viscosity for any one gas, the method is not so trustworthy as the second method. Here we may use either pendulums swinging through small arcs or disks oscillating in their own plane under the action of torsion. In both the measurement depends upon the rate at which the amplitude of oscillation diminishes.

Stokes, who first satisfactorily discussed the true nature of viscosity, tested the theory by a discussion<sup>7</sup> of the pendulum experiments of Dubuat (1786), Bessel (1826), and Baily (1832). From Baily's results he calculated '000104 (in metric units) as the coefficient of viscosity of air. Meyer<sup>8</sup> similarly deduced from Bessel's and Girault's<sup>9</sup> experiments the values '000275 and '000384. It is not in the least surprising that these are all pretty wide of the true value, seeing that the experimenters had not the special problem of finding the viscosity before them.

Meyer, to whom we owe a very complete series of valuable memoirs on the subject, has more recently experimented<sup>10</sup> with three different-sized pendulums. The values deduced for the viscosity were '000232, '000233, and '000184. The last number, given by the shortest pendulum, Meyer considers to be the best.

Maxwell,<sup>11</sup> Meyer,<sup>12</sup> and Kundt and Warburg<sup>13</sup> have experimented with oscillating disks. The methods of Maxwell and Meyer were so far similar that each used an arrangement of three horizontal circular disks, fixed centrally to the same vertical axis, and suspended by a torsion wire inside a receiver. The pressure and temperature of the air or gas inside could be adjusted to any desired values within certain limits. In Maxwell's apparatus, which Meyer adopted in his later researches, the moving disks vibrated between parallel fixed disks, which were perforated in the centre so as to allow the vertical suspended axis to pass freely through them. Each disk thus oscillated in its own plane between two parallel fixed surfaces. After the disks were set in position, and the air in the receiver brought to the desired temperature and pressure, the suspended disks were set in oscillation. This was effected magnetically, a small magnet fixed to the end of the suspended axis being acted upon by an external magnet suitably adjusted. Each disk, in its oscillations, dragged after it the layer of air in immediate contact with it; and in virtue of viscosity this oscillation was trans-

mitted with diminishing amplitude from layer to layer until the fixed disks were reached. In this setting and sustaining in motion a mass of gas, the disk was doing work; and, if left to itself and to the action of the torsion suspension, it oscillated with gradually diminishing range until it came to rest. The viscosity of the air was not the only retarding influence. The torsion wire had also a coefficient of viscosity; and then there was a possible resistance due to the slipping of the fluid at the surfaces of the disks. These various effects were discriminated by suitable modifications. Thus by placing the oscillating disks in contact with each other, and setting two of the fixed disks at measured distances above and below, Maxwell reduced the number of surfaces in contact with the fluid, and so increased the relative importance of the effect due to the wire's viscosity. Again, by diminishing the distances between the fixed and oscillating disks, he made the conditions more favourable to the effect (if any) due to the slipping. This latter effect was found to be so small as to be almost within the errors of observation; consequently Maxwell felt himself warranted in calculating the coefficient of viscosity on the assumption that there was no slipping.

Maxwell's final result in metric (C. G. S.) units for the coefficient of viscosity of dry air is

$$\mu = '0001878(1 + '00365\theta),$$

where  $\theta$  is the temperature in degrees Centigrade. Meyer's result is

$$\mu = '000100(1 + '0025\theta).$$

Maxwell found the effect of pressure to be inappreciable down to a pressure of 12 mm., and thus verified the deduction from theory.

Kundt and Warburg, in their experiments, used only one disk, which oscillated under the influence of a bifilar suspension between two fixed disks. They carried the pressure down to as low as 0.6 mm. At 20 mm. pressure the viscosity was the same as at the atmospheric pressure; but at lower pressures a slight diminution began to show itself. According to Crookes's later researches, this diminution becomes more and more marked at the

The manner in which the viscosity then remarkably with the manner in which the free path increases. It could not be expected that in such modified circumstances Maxwell's law would continue to apply. When the gas becomes so far rarefied that the mean free path of a molecule is not small compared to the space in which the gas is confined, the motion of the molecules cannot be treated statistically. Hence the deductions from a theory based upon the statistic method will no longer hold good.

Maxwell, Kundt and Warburg, and Crookes investigated by the disk method the viscosities of other gases, the values for which are compared below with the transpiration times of the same gases through capillary tubes. Maxwell also found that damp air, at 100 mm. pressure, and over water at about 20° C., was one-sixtieth less viscous than dry air at the same temperature. Kundt and Warburg found for water vapour, at 21° C. and 16 mm. pressure, the value

$$\mu = '0000975,$$

a little more than half that of air.

The results obtained by Meyer and Springmühl and by Puluj from their transpiration experiments agree well with those already given. In such experiments, however, the slipping of the gas over the solid surface has in certain circumstances a measurable effect. This slipping is measured by a certain coefficient, called the *Gleitungs-Koeffizient* by Helmholtz and Von Piotrowski. When this coefficient becomes appreciable, the gas in contact with the solid surface, instead of being at rest relatively to that surface, will be gliding over it with a finite velocity  $v$ . The circumstances of the motion will be very nearly the same if we remove a layer of the solid surface and replace it by fluid, the new surface of fluid in contact with the now solid surface being at rest. The thickness which must be so removed is the measure of the coefficient of slipping. Kundt and Warburg,<sup>14</sup> in their experiments with glass tubes, found this coefficient for dry air at about 20° C. to be

$$8/p \text{ centimetres,}$$

where  $p$  is the pressure in dynes per square centimetre, which is nearly the same as in millionths of an atmosphere. The value for hydrogen on glass is  $15/p$ . Hence at ordinary pressures and moderate exhaustions this coefficient is very small, becoming appreciable only at low pressures.

The relation between viscosity and temperature is indicated at once by Maxwell's and Meyer's formulæ given above. According to Maxwell, the viscosity is proportional to the absolute temperature. If in the kinetic theory the forces between the molecules are disregarded, that is, if the molecules are assumed to rebound after collision like elastic spheres, the relation deduced is that the viscosity varies as the square root of the absolute temperature. Hence the mutual molecular forces must be taken into account. Maxwell's experimental law would require any two molecules to repel each other with a force varying inversely as the fifth power of the distance. According to Meyer, however, the viscosity varies

according to a power of the absolute temperature less than unity, but greater than one-half. His results in this respect are corroborated by those of Kundt and Warburg, Puluj, and other later experimenters. The  $7/7$  power is probably not far from the truth. Hence we may give as the final value for the viscosity of dry air the expression

$$\mu = 0.0135(1 + 0.0223\theta).$$

The following table gives the values for the different gases, as determined by the different investigators, the viscosity of air being taken as unity.

	Graham	Maxwell	Meyer	Kundt and Warburg	Crookes
Air.....	1.000	1.000	1.000	1.000	1.000
Oxygen.....	1.112	...	1.035	...	1.112
Nitrogen.....	.971	...	...	...	.972
Carbonic oxide.....	.965	...	...	...	.972
Carbonic acid.....	.849	.852	.851	.856	.920
Hydrogen.....	.453	.516	.601	.453	.444

We do not here enter into the question of the thermodynamics of gases; enough to say that the relations between viscosity, diffusion, and thermal conductivity deduced by Maxwell from the kinetic theory have received remarkable corroboration from the experiments of Loschmidt, Stefan, Kundt and Warburg, and others. A discussion of the dynamical properties of gases would not, however, appear complete without mention of Crookes's so-called radiometer, even though these phenomena of high vacua are ultimately thermodynamic.

**Crookes's radiometer.** The typical form of the radiometer is a glass bulb, in which is hung a delicately poised arrangement of vanes. These, usually four in number, are fixed at the extremities of two light horizontal cross-arms, which are supported so as to be capable of easy rotation about a central vertical axis. The vanes or disks are set in vertical planes passing through the axis; and each has its one side bright, and the other blackened. For any rotation the motion of each vane is exactly alike: that is, either the bright faces all move first, or the dark faces do so. If the pressure of the gas inside the bulb is reduced to a very low exhaustion, the vanes under the action of light or heat will begin to rotate. The mere bringing the radiometer out of a dark region into daylight is enough to set up this rotation. In ordinary circumstances the dark faces are apparently repelled, and the vanes move round with their bright faces in advance.

The phenomenon is really a thermal one, as was demonstrated experimentally by Tait and Dewar.<sup>1</sup> Further, although it is most evident in high vacua (provided they are not too high), it can be produced in very moderate exhaustions by a suitable arrangement, as was long ago pointed out by Fresnel. Thus, if under the receiver of an ordinary air-pump a light disk be delicately poised near a parallel fixed surface, it will be apparently strongly repelled by this surface if the opposing surfaces are brought to different temperatures. This may be effectively done by means of a ray of sunlight. In this experiment, the essential condition is (as shown by Tait and Dewar) that the surfaces be at a distance comparable to the mean free path of the gaseous molecules. In Crookes's radiometer the free path is very long, and hence there is apparent repulsion between the blackened surfaces and the walls of the bulb. The reason simply is that, under the action of the radiant energy directed in upon the vanes, the dark faces, absorbing more energy, become warmer than the bright faces. Hence an inequality of temperature is produced in the highly rarefied gas, and this brings into existence a stress which displaces the vanes.

Liquid in the spheroidal state illustrates the same principle. That a drop of water may be supported over a hot surface without touching it requires an upward pressure. In other words, the vertical stress in the vapour and gas which separate the drop from the surface must be greater than the ordinary gaseous pressure all round the drop. This stress exists because of the difference of temperature between the drop and the surface, so that the pressure in the thin layer of vapour and gas is slightly greater in the vertical than in any horizontal direction.

A general notion of the manner in which this stress is sustained may be obtained from the following consideration. According to the kinetic theory of gases, the mean speed of the molecules is a function of the temperature—the higher the temperature the greater the speed. Hence molecules, impinging upon a surface at a higher temperature, and in a direction more nearly perpendicular to it, will rebound from that surface with increased momentum. The simultaneous motion of the surface, as if repelled, is then somewhat analogous to the recoil of a cannon when fired. The whole investigation of the question is, however, by no means simple. Maxwell has discussed it with characteristic lucidity in his latest contribution<sup>2</sup> to the dynamical theory of

gases. He finds that, when inequalities of temperature exist at a given point in a gas, the pressure is not the same in all directions. Its value in any given direction, in so far as it depends upon the temperature inequality, is proportional to the space-rate of change of the space-variation of the temperature in that direction—that is, to the second differential coefficient of the temperature with respect to the given direction. Hence the pressure will be greatest along the line for which this differential coefficient is a maximum. It appears that the pressure so called into existence by a possible temperature inequality is very minute at ordinary hydrostatic pressures, but becomes considerable when the pressure of the gas is made very small. If the inequality of temperature throughout the gas is due to the presence of small bodies, whose temperatures differ from the temperature of the gas at a distance from them, then the small bodies will be acted upon by the stresses set up, provided they are of the same order of smallness as the mean free path of the molecules. In the case of two such small bodies, there will be apparent repulsion between them if the bodies are warmer than the air at a distance from them, and attraction if they are colder. If one is warmer and the other colder, the action may be either attractive or repulsive, according to the relative sizes of the bodies and their exact temperatures. These results are obtained by considering only the stresses normal to the solid surfaces. When the tangential stresses are taken into account, then it appears that inequality of temperature, when the flow of heat becomes steady, cannot produce other than equilibrium in the material system immersed in the gas. Hence Maxwell believes that the explanation of Crookes's phenomenon must depend ultimately upon the slipping of the gas over the solid surface. If such slipping be permitted, its effect will be to diminish the tangential stresses acting on the solid surface without affecting the normal stresses; and hence the equilibrium will be destroyed. In attempting to express the conditions to be satisfied by the gas at the solid surface, Maxwell is led to the consideration of the phenomenon discovered by Osborne Reynolds<sup>3</sup> and named thermal transpiration. This phenomenon consists of a sliding of the gas over the surface of an unequally heated solid from the colder to the hotter parts. Maxwell considers the particular case of the slow steady flow of gas along a capillary tube of circular section, the temperature of which varies steadily from point to point. The amount of gas which passes through any section depends both upon the rate of change of pressure and the rate of change of temperature in passing along the axis of the tube. If the pressure is uniform there will be a flow of gas from the colder to the hotter end. If there is no flow of gas, the pressure will increase from the colder to the hotter end. The case of uniform temperature is the ordinary case of transpiration through capillary tubes, as discussed experimentally by Graham, Meyer, Puluj, and Kundt and Warburg. The experimental investigation of the first two cases seems at present hopeless, on account of the minuteness of the quantities to be measured. Reynolds experimented, not on capillary tubes, but on the passage of the gas through a porous plate, the temperatures being different on the two sides. (C. G. K.)

**PNEUMONIA**, or inflammation of the substance of the lungs, manifests itself in several forms which differ from each other in their nature, causes, and results,—viz., (1) Acute Croupous or Lobar Pneumonia, the most common form of the disease, in which the inflammation affects a limited area, usually a lobe or lobes of the lung, and runs a rapid course; (2) Catarrhal Pneumonia, Broncho-Pneumonia, or Lobular Pneumonia, which occurs as a result of antecedent bronchitis, and is more diffuse in its distribution than the former; (3) Interstitial Pneumonia or Cirrhosis of the lung, a more chronic form of inflammation, which affects chiefly the framework or fibrous stroma of the lung and is closely allied to phthisis.

**Acute Croupous or Lobar Pneumonia.**—This is the disease commonly known as inflammation of the lungs. It derives its name from its pathological characters, which are well marked. The changes which take place in the lung are chiefly three. (1) *Congestion*, or engorgement, the blood-vessels being distended and the lung more voluminous and heavier than normal, and of dark red colour. Its air cells still contain air. (2) *Red Hepatization*, so called from its resemblance to liver tissue. In this stage there is poured into the air cells of the affected part an exudation consisting of amorphous fibrin together with epithelial cells and red and white blood corpuscles, the whole forming a viscid mass which occupies not only

<sup>1</sup> *Proc. Roy. Soc. Edin., and Nature*, 1875.    <sup>2</sup> *Phil. Trans.*, 1879.

<sup>3</sup> *Proc. Roy. Soc.*, 1879.

the cells but also the finer bronchi, and which speedily coagulates, causing the lung to become firmly consolidated. In this condition the cells are entirely emptied of air, their blood-vessels are pressed upon by the exudation, and the lung substance, rendered brittle, sinks in water. The appearance of a section of the lung in this stage has been likened to that of red granite. It is to the character of the exudation, consisting largely of coagulable fibrin, that the term croupous is due. (3) *Grey Hepatization*. In this stage the lung still retains its liver-like consistence, but its colour is now grey, not unlike the appearance of grey granite. This is due to the change taking place in the exudation, which undergoes resolution by a process of fatty degeneration, pus formation, liquefaction, and ultimately absorption,—so that in a comparatively short period the air vesicles get rid of their morbid contents and resume their normal function. This is happily the termination of the majority of cases of croupous pneumonia, yet it occasionally happens that this favourable result is not attained, and that further changes of a retrograde kind take place in the inflamed lung in the form of suppuration and abscess or of gangrene. In such instances there usually exists some serious constitutional cause which contributes to give this unfavourable direction to the course of the disease. Further, pneumonia may in some instances become chronic, the lung never entirely clearing up, and it may terminate in phthisis. Pneumonia may be confined to a portion or the whole of one lung, or it may be double, affecting both lungs, which is a serious and often fatal form. The bases or middle of the lungs are the parts most commonly inflamed, but the apex is sometimes the only part affected. The right lung is considerably more frequently the seat of pneumonia than the left lung.

Many points in the pathology of this form of pneumonia remain still to be cleared up. Thus there is a growing opinion that it is not a simple lung inflammation, as was formerly supposed, but that, as regards its origin, progress, and termination, it possesses many of the characters of a fever or of a constitutional affection. An interesting and important fact in this connexion is the recent discovery by Friedländer and others of a micro-organism or bacillus in the blood, lungs, and other tissues in cases of pneumonia, which, when inoculated into certain lower animals, is followed by the symptoms and appearances characteristic of that disease. While it must be confessed that such inoculation experiments carried on in rabbits, guinea pigs, or mice are scarcely sufficient by themselves to settle the question of the specific and infectious nature of pneumonia as it affects the human subject, yet they are of distinct value as evidence pointing in that direction. Further, there are numerous instances on record in which this disease has appeared to spread as an epidemic in localities or in families in such a way as strongly to suggest the idea of infectiveness. Cases of this kind, however, are open to the question as to whether there may not coexist some other disease, such as a fever, of which the pneumonia present is but a complication. The whole subject of the pathology of pneumonia is still under investigation, and all that can in the meantime be affirmed is that it presents many features which render its phenomena unlike those of an ordinary inflammation, while on the other hand it has strong analogies to some of the specific fevers. As regards known causes, in the vast majority of instances an attack of pneumonia comes on as the result of exposure to cold as the exciting agent, while such conditions as fatigue and physical or mental depression are often traceable as powerful predisposing influences.

The symptoms of acute pneumonia are generally well marked from the beginning. The attack is usually ushered in by a rigor (or in children a convulsion), together with vomiting and the speedy development of the febrile condition, the temperature rising to a considerable degree— $101^{\circ}$  to  $104^{\circ}$  or more. The pulse is quickened, and there is a marked disturbance in the respiration, which is rapid, shallow, and difficult, the rate being usually accelerated to some two or three times its normal amount. The lips are livid, and the face has a dusky flush. Pain in the side is felt, especially should any amount of pleurisy be present, as is often the case. Cough is an early symptom. It is at first frequent and hacking, and is accompanied with a little tough colourless expectoration, which soon, however, becomes more copious and of a rusty brown colour, either tenacious or frothy and liquid. Microscopically this consists mainly of epithelium, casts of the air cells, and fine bronchi, together with granular matter and blood and pus corpuscles.

The following are the chief physical signs in the various stages of the disease. In the stage of congestion fine crackling or crepitation is heard over the affected area; sometimes there is very little change from the natural breathing. In the stage of red hepatization the affected side of the chest is seen to expand less freely than the opposite side; there is dulness on percussion, and increase of the vocal fremitus; while on auscultation the breath sounds are tubular or bronchial in character. With it may be, some amount of fine crepitation in certain parts. In the stage of grey hepatization the percussion note is still dull and the breathing tubular, but crepitations of coarser quality than before are also audible. These various physical signs disappear more or less rapidly during convalescence. With the progress of the inflammation the febrile symptoms and rapid breathing continue. The patient during the greater part of the disease lies on the back or on the affected side. The pulse, which at first was full, becomes small and soft owing to the interruption to the pulmonary circulation. Occasionally slight jaundice is present, due probably to a similar cause. The urine is scanty, sometimes albuminous, and its chlorides are diminished. In favourable cases, however severe, there generally occurs after six or eight days a distinct crisis, marked by a rapid fall of the temperature accompanied with perspiration and with a copious discharge of lithates in the urine. Although no material change is as yet noticed in the physical signs, the patient breathes more easily, sleep returns, and convalescence advances rapidly in the majority of instances. In unfavourable cases death may take place either from the extent of the inflammatory action, especially if the pneumonia is double, from excessive fever, from failure of the heart's action or general strength at about the period of the crisis, or again from the disease assuming from the first a low adynamic form with delirium and with scanty expectoration of greenish or "prune juice" appearance. Such cases are seen in persons worn out in strength, in the aged, and especially in the intemperate. Death may also take place later from abscess or gangrene of the lung; or again recovery may be imperfect and the disease pass into a chronic pneumonia.

The treatment of acute pneumonia, which at one time was conducted on the antiphlogistic or lowering principle, has of late years undergone a marked change; and it is now generally held that in ordinary cases very little active interference is called for, the disease tending to run its course very much as a specific fever. The employment of blood-letting once so general is now only in rare instances resorted to; but, just as in pleurisy, pain and difficulty of breathing may sometimes be relieved by the application of a few leeches to the affected side. In severe cases the cautious employment of aconite or antimony at the outset appears useful in diminishing the force of the inflammatory action. Warm applications in the form of poultices to the chest give comfort in many cases. Cough is relieved by expectorants, of which those containing carbonate of ammonia are specially useful. Any tendency to excessive fever may often be held in check by quinine. The patient should be fed with milk, soups, and other light forms of nourishment. In the later period of the disease stimulants may be called for, but most reliance is to be placed on nutritious aliment. After the acute symptoms disappear counter-irritation by iodine or a blister will often prove of service in promoting the absorption of the inflammatory products. After recovery is complete the health should for some time be watched with care.

When pneumonia is complicated with any other ailment or itself complicates some pre-existing malady, it must be dealt with on principles applicable to these conditions as they may affect the individual case.

*Catarrhal or Lobular Pneumonia* (Broncho-Pneumonia) differs from the last in several important pathological and clinical points. Here the inflammation is more diffuse and tends to affect lobules of lung tissue here and there, rather than one or more lobes as in croupous pneumonia. At first the affected patches are dense, non-crepitant, with a bluish red appearance tending to become grey or yellow. Under the microscope the air vesicles and finer bronchi are crowded with cells, the result of the inflammatory process, but there is no fibrinous exudation such as is present in croupous pneumonia. In favourable cases resolution takes place by fatty degeneration, liquefaction, and absorption of the cells, but on the other hand they may undergo caseous degenerative changes, abscesses may form, or a condition of chronic interstitial pneumonia be developed in both of which cases the condition passes into one of phthisis. Evidence of previous bronchitis is usually present in the lungs affected with catarrhal pneumonia. In the great majority of instances catarrhal pneumonia

occurs as an accompaniment or sequel of bronchitis either from the inflammation passing from the finer bronchi to the pulmonary air vesicles, or from its affecting portions of lung which have undergone collapse. It occurs most frequently in children, and is often connected with some pre-existing acute ailment in which the bronchi are implicated, such as measles or whooping cough. It likewise affects adults and aged people in a more chronic form as the result of bronchitis. Sometimes a condition of catarrhal pneumonia may be set up by the plugging of one or more branches of the pulmonary artery, as may occur in heart disease, pyæmia, &c.

The symptoms characterizing the onset of catarrhal pneumonia in its more acute form are the occurrence during an attack of bronchitis of a sudden and marked elevation of temperature, together with a quickened pulse and increased difficulty in breathing. The cough becomes short and painful, and there is little or no expectoration. The physical signs are not distinct, being mixed up with those of the antecedent bronchitis; but, should the pneumonia be extensive, there may be an impaired percussion note with tubular breathing and some bronchophony.

Acute catarrhal pneumonia must be regarded as a condition of serious import. It is apt to run rapidly to a fatal termination, but on the other hand a favourable result is not unfrequent if it is recognized in time to admit of efficient treatment. In the more chronic form it tends to assume the characters of chronic phthisis (see PHTHISIS). The treatment is essentially that for the more severe forms of bronchitis (see BRONCHITIS), where, in addition to expectorants, together with ammoniacal, æthereal, and alcoholic stimulants, the maintenance of the strength by good nourishment and tonics is clearly indicated. The breathing may often be relieved by light warm applications to the chest and back. Convalescence is often prolonged, and special care will always be required in view of the tendency of the disease to develop into phthisis.

*Chronic Interstitial Pneumonia or Cirrhosis of the Lung* is a slow inflammatory change affecting chiefly one portion of the lung texture, viz., its fibrous stroma.

The changes produced in the lung by this disease are marked chiefly by the growth of nucleated fibroid tissue around the walls of the bronchi and vessels, and in the intervesicular septa, which proceeds to such an extent as to invade and obliterate the air cells. The lung, which is at first enlarged, becomes shrunken, dense in texture, and solid, any unaffected portions being emphysematous; the bronchi are dilated, the pleura thickened, and the lung substance often deeply pigmented, especially in the case of miners, who are apt to suffer from this disease. In its later stages the lung breaks down, and cavities form in its substance as in ordinary phthisis.

This condition is usually present to a greater or less degree in almost all chronic diseases of the lungs and bronchi, but it is specially apt to arise in an extensive form from pre-existing catarrhal pneumonia, and not unfrequently occurs in connexion with occupations which necessitate the habitual inhalation of particles of dust, such as those of colliers, flax-dressers, stonemasons, millers, &c.

The symptoms are very similar to those of chronic phthisis (see PHTHISIS), especially increasing difficulty of breathing, particularly on exertion, cough either dry or with expectoration, sometimes copious and ferid. In the case of coal-miners the sputum is black from containing carbonaceous matter.

The physical signs are deficient expansion of the affected side—the disease being mostly confined to one lung—increasing dulness on percussion, tubular breathing, and moist sounds. As the disease progresses retraction of the side becomes manifest, and the heart and liver may be displaced. Ultimately the condition both as regards physical signs and symptoms takes the characters of the later stages of phthisis with colligative symptoms, increasing emaciation, and death. Occasionally dropsy is present from the heart becoming affected in the course of the disease. The malady is usually of long duration, many cases remaining for years in a stationary condition and even undergoing temporary improvement in mild weather, but the tendency is on the whole downward.

The treatment is conducted on similar principles to those applicable in the case of phthisis. Should the malady be connected with a particular occupation, the disease might be averted or at least greatly modified by early withdrawal from such source of irritation.

PNOM-PENH, the capital of CAMBODIA (see vol. iv. p. 725).

PO, the largest river of Italy, traverses the whole length of the great plain between the Alps and the Apennines, which was in the Miocene period an arm of the sea connecting the Adriatic with the Mediterranean by what is now the Col d'Altare or Col di Cadibona and has gradually been filled by detritus from the surrounding highlands. That its course lies much nearer the Apennines than the Alps is evidently due to the fact that the tributaries from the loftier range on the north, whether in the form of glacier or stream, have all along been much more powerful than the tributaries from the south. The total length of the river from its conventional source to the mouth of the principal channel is 417½ miles, and the area of its basin, which includes portions of Switzerland and Austria, is estimated at 26,798 square miles. The general course of the river has been already described in ITALY (vol. xiii. p. 435).

The Po forms a very extensive delta, and is probably one of the most active of all rivers in the work of denudation. Prony has calculated that between 1200 and 1600 the delta advanced at the rate of 80 feet per annum; and between 1600 and 1804 the rate is said to have been as much as 230 feet. This advance has naturally been attended by great changes in the course and size of the several channels. Ravenna, for example, once a great port, now stands on dry land 4 miles from the sea. The modern lagoons of Comacchio, which stretch southwards from the delta, are being artificially reclaimed by the help of the alluvial deposits.

In its ordinary condition the Po has a depth between Piacenza and the mouth of the Ticino of from 5 to 10 feet, and between the mouth of the Lambro and that of the Adde of about 14 or 15 feet. Lower down the depth occasionally exceeds 40 feet. Permanent fords exist only in the upper Po, and between the mouths of the Ticino and the Lambro. In times of great drought the bed is quite dry at Rovello, and fords appear below Casalmaggiore and at Borgoforte, where the French and Germans crossed in 1796, 1807, 1813, and 1814: but in general the river forms a complete barrier both to foot and horse. The principal points where crossing is effected by ferries or bridges are \*Moncalieri, Turin, \*Casale Monferrato, Frassinato, \*Valenza, \*Mezzana Corri, \*Piacenza, Cremona, Casalmaggiore, Brescello, \*Borgoforte, San Benedetto, Origgio, \*Ossobello, Pontelagoscuro, Francolino. Railway bridges exist at the places distinguished by an asterisk.

The river in general is at its fullest in May and June, and at its lowest in January (see details in Lombardini's elaborate study on the lower Po in *Memorie del Reale Istituto Lombardo*, Milan, 1879). The ordinary floods on the Po are attended with little danger: but at intervals sometimes of a few sometimes of many years they become events of the gravest national concern. Those of 1651 and 1793 are among the most destructive recorded in history, and in the present century the more memorable are those of 1839, 1846, 1855, 1857, 1863, 1872, and 1879. In 1872 1150 square miles of country between the Reno and the Adige were submerged, the district about Modena was turned into a lake. The people of Ravenna saved the rest of their town only by sacrificing the front row of houses to form a temporary embankment, and it was only by the wisely conducted energy of its inhabitants that Origgio was kept from destruction. During April and May 1879 the rainfall was exceptionally heavy, the quantity for May alone being equal to more than a third of the annual total. The result was a rise in all the tributaries of the Po, and on May 30 the flood in the main river was 21 feet above low water at Mezzana Corri. A breach 720 feet long in the embankment between Bonizzo and Borgoforte caused the submergence of 155 square miles in the provinces of Mantua, Modena, and Ferrara, and involved in its repair a national expenditure of £33,470.

Of the £5,502,231 devoted by the Government to the regulation of the rivers of Italy in the twenty years 1861–1880, £2,237,572 of the rivers of Italy in the twenty years 1861–1880, £2,237,572 had to be appropriated to the Po and its tributaries. Nowhere in Europe except in Holland has the system of embankment been carried to such perfection on so extensive a scale. A wide bed for the river at its height is enclosed for long distances by a massive master-dyke or *foido*, and in the space between this and the ordinary channels suitable areas are often enclosed by secondary dykes or *golene*. The following figures show the extent of the system in 1859:—

	Length of Embankment.	Frodo.	Golena.
Po.....	Miles. 509.97	Miles. 71.93	Miles. 438.03
Adige.....	156.12	109.81	46.30
Tartaro and Po di Levante.....	148.80	35.62	112.68
Reno.....	146.72	33.68	113.04
Panaro.....	100.34	48.26	52.07
Secchia.....	89.75	23.21	61.54

Recent researches (see Helbig, *Die Italiker in der Po-Ebene*, Leipzig, 1879) show that the lower valley of the Po was at an early period occupied by people of the Palæolithic and Neolithic stages of civilization, who built houses on piles along the swampy borders of the streams. It is possible that even they may have begun by crude dykes the great system by which the waters are now controlled; at least it is certain that these works date their origin from pre-Roman antiquity. Pliny refers them to the Etruscans, who occupied the country before the arrival of the Gauls. The reclaiming and protecting of the riparian lands went on rapidly under the Romans, and in several places the character of the ground, still remarkably distinct, shows the character of some of the agricultural colonics. During the time of the barbarian invasions much of the protective system was allowed to fall into decay; but the later part of the Middle Ages saw the works resumed and carried out with great energy, so that the main features of the present arrangement were in existence by the close of the 15th century.

The usual name for the Po among Greek and Latin authors was *Padius* (Πάδις); but the Greek writers of the empire began to apply to it the poetic name of *Eridanus*, familiar in the Phaëthon myth.

POCHARD, POCKARD, or POKER,<sup>1</sup> names properly belonging to the male of a species of Duck (the female of which is known as the Dunbird), the *Anas ferina* of Linnaeus, and *Fuligula* or *Ethya ferina* of later ornithologists—but names very often applied by writers in a general way to most of the group or Subfamily *Fuliginæ*, commonly called Diving or Sea-Ducks (cf. DUCK, vii. p. 505). The Pochard in full plumage is a very handsome bird, with a coppery-red head, on the sides of which sparkle the ruby irides of his eyes, relieved by the greyish-blue of the basal half of his broad bill, and the deep black of his gorget, while his back and flanks appear of a light grey, being really of a dull white closely barred by fine undulating black lines. The tail-coverts both above and below are black, the quill feathers brownish-black, and the lower surface of a dull white. The Dunbird has the head and neck reddish-brown, with ill-defined whitish patches on the cheeks and chin, the back and upper tail-coverts dull brown, and the rest of the plumage, except the lower tail-coverts, which are brownish-grey, much as in the Pochard. This species is very abundant in many parts of Europe, northern Asia, and North America, generally frequenting in winter the larger open waters, and extending its migrations to Barbary and Egypt, but in summer retiring northward and inland to breed, and is one that certainly seems to have profited by the legislative protection lately afforded to it in Britain, for, whereas during many years it had but a single habitual breeding-place left in England, it is now known to have several, to some of which it resorts in no inconsiderable numbers. American examples seem to be slightly larger and somewhat darker in colour, and hence by some writers have been regarded as specifically distinct under the name of *Fuligula americana*; but America has a perfectly distinct though allied species in the celebrated Canvas-back Duck, *F. mellisieriana*, a much larger bird, with a longer, higher,

<sup>1</sup> The derivation of these words, in the first of which the *ch* is pronounced hard, and the *s* in all of them generally long, is very uncertain. Cuvier has *Pocheculier*, which he renders "Shoueler," nowadays the name of a kind of Duck, but in his time meaning the bird we commonly call SPOONBILL (*q.v.*). Littré gives *Pochard* as a vulgar French word signifying drunkard. That this word would in ordinary use become the English Pochard or Poker may be regarded as certain; but then it is not known to be used in French as a noun.

and narrower bill, which has no blue at the base, and, though the plumage of both, especially in the females, is very similar, the male Canvas-back has a darker head, and the black lines on the back and flanks are much broken up and further asunder, so that the effect is to give these parts a much lighter colour, and from this has arisen the bird's common though fanciful name. Its scientific epithet is derived from the freshwater plant, a species of *Falkisneria*, usually known as "wild celery," from feeding on which its flesh is believed to acquire the delicate flavour that is held in so great a repute. The Pochard and Dunbird, however, in Europe are in much request for the table (as the German name of the species, *Tafelente*, testifies), though their quality in this respect depends almost wholly on the food they have been eating, for birds killed on the sea-coast are so rank as to be almost worthless, while those that have been frequenting fresh water are generally well-tasted.<sup>2</sup>

Among other species nearly allied to the Pochard that frequent the northern hemisphere may be mentioned the Scaup-Duck, *F. marila*, with its American representative *F. affinis*, in both of which the male has the head black, glossed with blue or green; but these are nearly always uneatable from the nature of their food, which is mostly gathered at low tide on the "scalps" or "scalps"—as the banks on which mussels and other marine molluscs grow are in many places termed. Then there are the Tufted Duck, *F. cristata*—black with a crest and white flanks—and its American equivalent *F. collaris*, and the White-eyed or Castaneous Duck, *F. nyroca*, and the Red-crested Duck, *F. rufigula*—both peculiar to the Old World, and the last, conspicuous for its red bill and legs, well known in India. In the southern hemisphere the genus is represented by three species, *F. capensis*, *F. australis*, and *F. novæ-zelandiæ*, whose respective names indicate the country each inhabits, and in South America exists a somewhat divergent form which has been placed in a distinct genus as *Metopiana peposaca*.

Generally classed with the *Fuliginæ* is the small group known as the Eiders, which differ from them in several respects: the bulb at the base of the trachea in the male, so largely developed in the members of the genus *Fuligula*, and of conformation so similar in all of them, is here much smaller and wholly of bone; the males take a much longer time, two or even three years, to attain their full plumage, and some of the feathers on the head, when that plumage is completed, are always stiff, glistening, and of a peculiar pale-green colour. This little group of hardly more than half a dozen species may be fairly considered to form a separate genus under the name of *Somateria*. Many authors indeed have—unjustifiably, as it seems to the present writer—broken it up into three or four genera. The well-known Eider, *S. mollissima*, is the largest of this group, and, beautiful as it is, is excelled in beauty by the King-Duck, *S. spectabilis*, and the little *S. stelleri*. Space fails here to treat of the rest, but the sad fate which has overtaken one of them, *S. labradoria*, has been before mentioned (BIRDS, vol. iii. p. 735); and only the briefest notice can be taken of a most interesting form generally, but obviously in error, placed among them. This is the Logger-head, Racehorse, or Steamer-Duck, *Micropterus* (or more properly *Tachyeres) cinereus* of the Falkland Islands and Straits of Magellan—nearly as large as a tame Goose, and subject to the, so far as known, unique peculiarity of losing its power of flight after reaching maturity. Its habits have been well described by Darwin in his *Journal of Researches*, and its anatomy is the subject of an excellent paper in the Zoological Society's *Transactions* (vii., pp. 493–501, pls. lviii.–lxii.) by Prof. R. O. Cunningham.

(A. N.)

POCOCK, EDWARD (1604–1691), one of the most eminent of English Oriental and Biblical scholars, was born in 1604, the son of a Berkshire clergyman, and received his education up to his fourteenth year at the free school of Tame in Oxfordshire and then at Oxford, where he became scholar of Corpus Christi College in 1620 and fellow in 1628. The foundation of his Eastern learning was laid at Oxford under Matthias Pasor, son of the better

<sup>2</sup> The plant known in some parts of England as "willow-weed"—not to be confounded, as is done by some writers, with the willow-herb (*Epilobium*)—one of the many species of *Polygonum*, is especially a favourite food with most kinds of Ducks, and to its effects is attributed much of the fine flavour which distinguishes the birds that have had access to it.

<sup>3</sup> Cognate with *scallop*, and the Dutch *schelp*, a shell.

<sup>4</sup> Icelandic, *Edur*.

known George Pasor, who had been driven to England by the troubles in the Palatinate, and he subsequently received instruction from the learned W. Bedwell. The first fruit of his studies was an edition from a Bodleian MS. of the four New Testament epistles which were not in the old Syriac canon, and were not contained in European editions of the Peshito. This was published at Leyden at the instigation of G. Vossius in 1630, and in the same year Pocock sailed for Aleppo as chaplain to the English factory. At Aleppo he made himself a profound Arabic scholar and collected many valuable MSS. At this time Laud was busy with the learned collections with which he afterwards enriched his university, and Pocock became known to him as one who could help his schemes. A correspondence ensued, and ultimately Laud resolved to set up an Arabic chair at Oxford and to invite Pocock home to fill it. The invitation was accepted, and the lecturer entered on his duties on August 10, 1636, but next summer sailed again for Constantinople with the archbishop's consent to prosecute further studies and collect more books, and remained there for about three years. When he returned to England Laud was in the Tower; and, though he had taken the precaution to place the Arabic chair on a permanent footing, a time soon followed in which to have been a protégé of the archbishop was a dangerous distinction. Pocock does not seem to have been an extreme churchman or to have meddled actively in politics, but his views were decided enough to make him objectionable to the Parliamentary party, and to bring on him many troubles not only at Oxford but in his parish of Childrey, where he accepted a college living in 1643. On the other hand his rare scholarship and personal qualities raised him up influential friends even among men of the opposite party in church and state, foremost among these being Selden. Through the offices of these friends he was even advanced in 1648 to the chair of Hebrew, though as he could not take the engagement of 1649 he lost the emoluments of the place very soon after, and did not recover them till the Restoration. All these cares seriously hampered Pocock in his studies, as he complains in the preface to his *Eutychius*; he seems to have felt most deeply the attempts to remove him from Childrey, where he attended to his parochial work with the same modest and diligent zeal that marks him as a scholar. But he continued to work hard; in 1649 he published the *Specimen Historiæ Arabum*, that is, a short account of the origin and manners of the Arabs, taken from Barhebræus (Abulfaraj), with a mass of learned notes from a vast number of MS. sources which are still highly valuable to the student of Oriental history. This was followed in 1655 by the *Porta Mosæ*, extracts from the Arabic commentary of Maimonides on the Mishna, with translation and very learned notes;<sup>1</sup> and in 1656 by the annals of *Eutychius* in Arabic and Latin, a work of great value which has not found an editor since. He also gave active assistance to Walton's polyglott, and the preface to the various readings of the Arabic Pentateuch is from his hand. After the Restoration Pocock's political and pecuniary troubles were removed, but the reception of his complete edition of the Arabic history of Barhebræus (*Greg. Abulfaragii Historia Dynastiæ*), which he dedicated to the king in 1663, showed that the new order of things was not very favourable to profound scholarship. After this his most important works were his English commentaries on Micah (1677), Malachi (1677), Hosea (1685), Joel (1691),—admirable in every way, and still thoroughly worth reading. An Arabic translation of Grotius *De Veritate* which appeared in 1660 may also be mentioned as a proof of Pocock's interest in

the propagation of Christianity in the East. This was an old plan which he had talked over with Grotius at Paris on his way back from Constantinople.

Pocock married in 1646 and died in 1691. One of his sons, Edward, published several contributions to Arabic literature—a fragment of Abdullatif's description of Egypt and the *Philosophus Autodidactus* of Ibn Tofail.

The theological works of Pocock were collected in 2 vols. folio, in 1740, with a tedious but curious account of his life and writings by L. Twells.

POCOCKE, RICHARD (1704–1765), distantly related to the preceding, was the son of Richard Pocke, head master of the free school at Southampton, where he was born in the year 1704. He received his school learning under his father, and his academical education at Corpus Christi College, Oxford, where he took his various degrees. He commenced his travels in the East in 1737, and returned in 1742. In 1743 he published his *Observations on Egypt*, under the general title of *A Description of the East and some other Countries*. In 1744 he was made precentor of Waterford; and in 1745 he printed the second volume of his travels, under the title of *Observations on Palestine, or the Holy Land, Syria, Mesopotamia, Cyprus, and Candia*. In 1756 Pocke was promoted to the bishopric of Ossory; in July 1765 he was translated to the see of Meath, and in September following he died suddenly of apoplexy, whilst engaged in visiting his diocese.

PODIEBRAD, GEORGE OF (1420–1471), king of Bohemia, was the son of Herant of Podiebrad, a Bohemian nobleman, and was born 6th April 1420. After the death of the emperor Sigismund he took up arms against Albert of Austria, who was finally compelled to raise the siege of Tabor and retreat to Prague. On the death of Patzek in 1444 George of Podiebrad became the recognized head of the Calixtines or Utraquists, and was chosen to represent them as one of the two governors of Bohemia during the minority of Ladislaus the son of Albert. After some years of conflict with the Catholic party he was in 1451 recognized as sole governor. Following a policy of conciliation, he made no opposition to the accession of Ladislaus in 1453, who repeated to the Bohemians the promises made by Sigismund. The Catholic predilections of Ladislaus rendered him in a great measure blind to the obligations into which he had entered, but the result was silently to strengthen the influence of George of Podiebrad, who on the death of Ladislaus in 1457 was chosen king of Bohemia (March 1458), and on May 7, 1459, was crowned by Catholic bishops, promising on his part due obedience to the church. This effort at a reconciliation was, however, soon seen to be futile. In 1462 Pope Pius II. refused the ratification of the *compactata*, agreed upon in 1433, and still no basis of a settlement had been found when Pius died in November 1464. The new pope, Paul II., at once brought matters to a crisis by issuing against George of Bohemia the ban of excommunication, and a summons for a crusade to crush his authority. To this George replied by a letter of grievances to kings and princes, and an appeal to a general council. The summons of Paul II. did not awaken any general response, and, although Matthias of Hungary was proclaimed king of Bohemia, George successfully resisted all attempts to wrest from him his dominion, and in July 1470 Matthias agreed to an armistice. George died March 22, 1471, and was succeeded by Ladislaus, eldest son of Casimir IV.

See Markgraf, *Ueber das Verhältniss des Königs Georg von Böhmen zu Papst Pius II.*, 1867; Richter, *Georg von Podiebrads Bestrebungen*, 1863; Jordan, *Das Königthum Georgs von Podiebrad*, 1867; Bachmann, *Ein Jahr böhmischer Geschichte*, 1876.

PODOLIA, a government of south-western Russia, having Volhynia on the N., Kieff and Kherson on the E

<sup>1</sup> Pocock was justly impressed with the fact that the best parts of Rabbinic literature belong to the Jews who wrote in Arabic.

and S., Bessarabia on the S.W., and Galicia (Austria) on the W., from which last it is separated by the Zbrutch, or Rodvotcha, a tributary of the Dniester. It has an area of 16,223 square miles, extending for 200 miles from north-west to south-east on the left bank of the Dniester. In the same direction two ranges of hills, nearly parallel, and separated by the Bug, traverse the government; they are ramifications of the so-called "Avratynsk heights." One of these ranges runs parallel to the Dniester at a distance of some 40 miles, and reaches a maximum elevation of 1185 feet in the northern districts, sending a lateral branch to the Dniester at Kamenets. The other range, entering also from the north-west, follows the boundaries of the government of Kieff on the left bank of the Bug; its highest eminences do not exceed 1050 feet. The geological structure of Podolia is in accordance with the above-mentioned orographical features; a strip of land to the east of the Bug belongs to the Huronian granitic region of the Dnieper, granites and aplites (granulites) appearing also in the bed of the Bug, and being covered with Quaternary deposits only, while the remainder of the province, towards the west, is covered with Tertiary (Miocene). In the deep valleys of the rivers, older formations—the Cretaceous and Silurian, as also sometimes the granites—appear from beneath the Tertiary. The whole is covered with a boulder-clay, mostly containing debris of the local rocks, and with loess, the origin of both still being a subject of controversy among Russian geologists. Two large rivers, with numerous tributaries, water the government,—the Dniester, which forms its boundary with Bessarabia and is navigable throughout its length, and the Bug, which flows almost parallel to the former in a higher, sometimes swampy valley, and is broken at several places by strong rapids. The Dniester is an important channel for trade, no less than 30,000 tons of corn, spirits, and timber being exported every year from its eighteen ports, the chief of which are Moghileff, Kalus, Zhvanets, and Porog. The rapid smaller tributaries of the Dniester supply numerous flour-mills with motive power. The soil is almost throughout "black-earth," and Podolia is one of the most fertile provinces of Russia. Forests cover about 245,000 acres. Marshes occur only on the Bug. The climate is moderate, the average temperature of the year at Kamenets being 48°·3 (24°·5 in January, 69° in July).

The population, which was 2,242,650 in 1881, and is now estimated at 2,335,000, consists chiefly of Little Russians, Poles (about 12 per cent.), and Jews (about 13 per cent.), of whom some 2000 are agriculturists. There are besides about 300 Armenians, some 2500 Germans, and nearly 45,000 Moldavians. There are many Nonconformists among the Russians, Tultchin being the seat of their bishops and a centre of propaganda. The chief occupation is agriculture, 58 per cent. of the surface being under crops, and the average harvests of recent years reaching 3,352,000 qrs. of corn and 453,000 qrs. of potatoes. The chief crops are wheat, Indian corn, oats, rye, potatoes, and beetroot. No less than 2,500,000 qrs. of corn are exported every year to Austria or to Odessa. Gardening is in a flourishing condition, and fruit is largely exported to the interior; the vine is cultivated, mostly for grapes, but partly also for wine; the culture of tobacco is a considerable source of income. Cattle-breeding is less developed, owing to a want of grazing grounds and meadows. Horned cattle—a mixture of the Hungarian and Bessarabian breeds—are, however, exported to Moscow and to Austria. Finer breeds of sheep are raised in the proportion of two-fifths of the whole number. In 1881 Podolia had 169,000 horses, 432,000 horned cattle, 513,000 sheep, and 307,000 swine. Bees are kept throughout the territory, and honey is exported. Sericulture has developed considerably of late years, and will probably take an important position, owing to the climate. Agriculture and cattle-breeding are on the whole declining. Lately manufactures have grown rapidly. In 1885 they already employed 14,450 hands, but produced only to the value of 5,331,000 roubles. Fourteen years later they employed more than 20,000 hands, and their yearly production was valued at 29,111,000 roubles. The first place is taken by beetroot sugar works (15,800 hands; £1,033,000), after which come distilleries (21,372,000), sugar refineries (2287,100), flour-mills (£134,500),

tobacco manufacture (£32,200), the woollen cloth industry, and several smaller manufactures (spirits, leather, soap, candles, machinery, and agricultural implements). An active trade is carried on with Austria, especially through the Isakovets and Gussyatin custom-houses,—corn, cattle, horses, skins, wool, linseed, and hemp seed being exported, in exchange for wooden wares, linen, woollen stuffs, cotton, glass, and agricultural implements. The trade with the interior is also carried on very briskly, especially at the twenty-six fairs, the aggregate returns of which exceed 3,000,000 roubles; the chief are at Balta and Yarmolinty. Podolia is traversed by a railway which runs parallel to the Dniester, from Lemberg to Odessa, and has two branch lines to Kieff (from Zhmerinka) and to Poltava (from Balta). Primary schools are better than in many central provinces of Russia, and Kamenets-Podolsk has of late years begun to show some development of intellectual life. The publications of the provincial assembly and the memoirs of the historical and statistical committee of the government are especially worthy of notice. Podolia is divided into twelve districts, the chief towns of which are—Kamenets-Podolsk, capital of the government (22,650), Balta (22,450), Bratslaff (6550), Gaysin (9450), Letitcheff (4800), Litin (7100), Moghileff-on-Dniester (18,150), Novaya Ushitsa (4500), Olgopol (6950), Proskuroff (11,750), Vinnitsa (18,800), and Yampol (4300). The following towns have municipal institutions:—Bar (7800), Khmelnik (7800), Nemiroff (5450, has a lyceum), Salnitsa (3300), Staraya Ushitsa (3700), Verbovets (2150), and Tultchin (11,220), besides many *myestetchki*, having Polish municipal institutions.

*History.*—The country has been inhabited since the beginning of the Neolithic period. In the 5th century B.C. it was already known to geographers, and Herodotus mentions it as the seat of the Alazones and Neuri, who were followed by the Dacians and Getæ. The Romans left traces of their rule in the Wall of Trajan, which stretches through the modern districts of Kamenets, Ushitsa, and Proskuroff. Many nationalities passed through this territory, or settled within it for some time, during the great migrations, leaving traces in numerous archaeological remains. The annals of Nestor mention that the Slavonians, Bujanes, and Dulebes occupied the Bug, while the Tiverts and Uglitches were settled on the Dniester. They were conquered by the Avars in the 7th century. Oleg extended his rule over this territory—the *Ponizie*, or lowland, which became later a part of the principalities of Volhynia, Kieff, and Galicia. In the 13th century the *Ponizie* was plundered by the Mongols; a hundred years afterwards Olgerd freed it from this rule, annexing it to Lithuania under the name of *Podolia*, a word which has the same meaning as *Ponizie*. After the death of Witovt Podolia was annexed to Poland, with the exception of its eastern part—the province of Bratslaff—which remained under Lithuania until its union with Poland. The Poles retained Podolia until the third division of Poland in 1793, when it was taken by Russia, which instituted the present government of Podolia in 1796.

PODOLSK, a district-town of Russia, in the government of Moscow, is situated 23 miles to the south of the capital, at the junction of the two main roads going from Moscow to the Crimea and to Warsaw, and within a mile from the Podolsk railway station. It is picturesquely built on the hilly banks of the Pakhra, here crossed by an elegant suspension bridge for carriages as well as by the railway bridge. Down to 1781, when it became a district town, the wealthy village of Podol was a dependency of the Danilooff monastery of Moscow, and it still maintains many of the features of a suburb of that city. The numberless caravans of cars and sledges which before the opening of the southern railway carried on the entire transport of merchandise to and from Moscow (as they still to some extent continue to do) had their chief halting place at Podolsk before setting out on a long journey, or before entering the capital; the principal occupation of the inhabitants was accordingly to keep inns and taverns, and to supply the caravans with provisions and other necessities of travel. The merchants of Podolsk prefer to carry on their trade at Moscow, and in itself the town has no commercial importance. Still, notwithstanding the recent modifications in traffic produced by the railway system, the population of Podolsk (11,000 in 1881) is increasing. The limestone quarries in the neighbourhood, at the confluence of the Desna and Pakhra, supply the capital with a good building material, while a steam factory of cement, lime, and bricks employs 900 hands and has an annual

production of about £20,000. A paper-mill close to Podolsk has an annual production of about £15,000.

PODOPHYLLIN, a popular remedy which is much used by those who are averse to the employment of calomel and other mercurial preparations, and hence has been, called vegetable mercury. The drug, as used in medicine, is obtained from the rhizome of the American mandrake or May apple, *Podophyllum peltatum*, L., an herbaceous perennial belonging to the natural order *Berberidaceæ*, indigenous in woods in Canada and the United States. The plant is about a foot high, bearing two peltate, deeply-divided leaves, which are about 5 inches in diameter, and bear in the axil a solitary, stalked, white flower about the size and shape of the garden anemone, with six or more petals and twice as many hypogynous stamens. The fruit is ripe in July, and is an oval, yellowish, fleshy berry containing twelve or more arillate seeds. The rhizome, as met with in commerce, occurs in cylindrical pieces two or three inches long and about  $\frac{1}{4}$  inch in diameter, of a chocolate or purplish brown colour, smooth and slightly enlarged where the juncture of the leafy stem is indicated by a circular scar on the upper and a few broken rootlets on the under side. The odour is heavy and disagreeable, and the taste acrid and bitter.

Podophyllin is a resinous powder obtained by precipitating an alcoholic tincture of the rhizome by means of water acidulated with hydrochloric acid. It varies in colour from greyish to bright yellow or greenish brown, the first-named being the purest. The drug has been the subject of numerous chemical investigations, the most recent of which (Podwyssotzki, in *Ztschr. f. Russland*, xx. 777) indicates that its activity is due to a definite resinous compound which has been named by its discoverer *podophyllotoxin*; another constituent named *podophylloquercetin* has neither emetic nor purgative properties, but appears to be the cause of the griping pains which sometimes accompany the action of podophyllin; a third substance, *podophyllic acid*, has no medicinal action. *Podophyllotoxin* is a bitter amorphous principle soluble in weak alcohol and in hot water, ether, and chloroform, but insoluble in petroleum spirit. It is split up by the action of alkalies into a resin-acid named *picropodophyllic acid*, which is inert, and a very acrid substance, *picropodophyllin*, which crystallizes in delicate silky needles. *Picropodophyllin* is insoluble in water, and almost insoluble in spirit of less than 80 per cent., but is rendered soluble when united to the *picropodophyllic acid*. *Podophylloquercetin* crystallizes in short needles of a yellow colour and metallic lustre. It is soluble in ether and alcohol, and forms a compound with acetate of lead which is soluble in acetic acid and can be sublimed in shining yellow crystals, and which on exposure to the air gradually becomes green. *Podophyllic acid* is insoluble in water and in ether, but soluble in alcohol. In medicine podophyllin is employed for torpor of the liver and obstinate constipation, arising from sedentary employment, imprudence in diet, and irregularity of habits. In small doses it acts as a slow and gentle laxative, especially if combined with henbane and belladonna, but in large doses it is an irritant hydragogue cathartic, the action of which persists for some time. The usual dose as a laxative and mild hepatic stimulant is about  $\frac{1}{4}$  of a grain, but the samples met with in commerce vary considerably in strength, and act with varying effect upon different individuals. Specimens having a greenish tint should be avoided, since they probably contain *podophylloquercetin* and tend to cause severe griping. In large doses it appears to lose its stimulant action on the liver. Podophyllin is official in the pharmacopœias of Great Britain, India, France, Russia, and the United States.

POE, EDGAR ALLAN (1809-1849), is the most interesting figure in American literature, and his life furnishes the most extraordinary instance on record of systematic misrepresentation on the part of a biographer. The greater part of his short working life was passed in intense and unremitting literary toil, and no poems or romances were ever produced at greater expense of brain and spirit than his. Yet, till lately, when Mr J. H. Ingram, the careful editor of Poe's works, undertook to collect the plain facts of the poet's life, the current statement and belief were that his strange tales and poems were flung off from a distempered imagination in the intervals of degraded debauchery. This myth was studiously floated by his first

biographer, Griswold, and found readier acceptance with the public owing to the weird and horrible character of much of his imaginative work. Griswold's story of a life wayward and irregular from hapless beginning to disgraceful close was just what people were prepared to believe about a genius so eccentric and with such a turn for dark mysteries, horrible crimes, inhuman doings and sufferings. That the author of such works should have been expelled from the university and from the army, and from situation after situation when he tried to make a living by literature, all owing to the gross irregularity of his habits, and should finally have died in a hospital in a fit of intoxication, seemed credible enough when affirmed by a self-constituted biographer. Many of Griswold's allegations were denied at the time, but the denials were local and isolated, and the truth had no chance against the systematic libel, repeated as it was in many editions, till Mr Ingram prepared a regular and authoritative memoir.<sup>1</sup>

There was a sufficient mixture of truth with falsehood to make Griswold's story plausible. It was not quite correct to describe Poe as the son of strolling players, but his father, a man of good family, had married an actress and taken to the stage as a profession. Their son was born in Boston, Mass., January 19, 1809; and father and mother died in 1811 when he was a child. The orphan was adopted by his godfather, Mr Allan, a wealthy merchant, and from his eighth till his thirteenth year (1816-1821) was placed at school in England. Thence he was transferred to an academy at Richmond, Virginia, and thence at the age of seventeen to the university of Virginia at Charlottesville. Mr Allan was childless, and apparently treated his adopted son as his own child. Why Poe left the university after one session is not clearly explained, but it has been ascertained that he was not expelled, but on the contrary was honourably distinguished as a student, although it is admitted that he had contracted debts and had "an ungovernable passion for card-playing." These debts may have been sufficient cause for a quarrel with Mr Allan. Poe disappeared for two years, setting out for Europe to join the Greeks in their fight for independence. Reappearing at Richmond in 1829, he stayed at home for a year, and then was entered as a military cadet at West Point. But all his ambitions by this time were towards literature; he neglected his duties, disobeyed orders, and was dismissed from the service of the United States. What he did for two years after is not ascertained, but in 1833 he reappeared as the successful competitor for a prize offered by a Baltimore newspaper for a prose story. From that time he subsisted by literature. Mr Allan had married again, and died soon afterwards, leaving an heir by his second wife, and "not a mill," as Griswold puts it, to Poe.

It is chiefly in his account of Poe's literary career that Griswold has been guilty of slandering the subject of his biography, representing him as rendered incapable of permanent employment by his intemperate habits. There would seem to be not the slightest foundation for this coarse slander. During the fifteen years of his literary life Poe was connected with various newspapers and magazines in Richmond, New York, and Philadelphia, and there is unanimous testimony that, so far from being an irregular contributor, he was a model of punctuality and thoroughness, and took a pride in these homely virtues. His connexion was not in any one case "severed by his irregularities." He wrote first for the *Southern Literary Messenger* in Richmond, and edited it for some time; then, in 1837, he removed to New York, and wrote criticisms and did editorial work for the *New York Quarterly Review*;

<sup>1</sup> See his *Works of Edgar Allan Poe*, 4 vols., 1874-75.

then, after a year, with a prospect of more lucrative employment, he removed to Philadelphia, and for four years was the mainstay of *Graham's Magazine*. His literary work was poorly paid for, though some of his most powerful tales—*Hans Pfaal*, *Arthur Gordon Pym*, *Ligeia*, *The Hound of Usher*, *The Murders in the Rue Morgue*, *Murder on the Coast*, *The Descent into the Maelström*—were among Poe's contributions to these periodicals. Not unnaturally he conceived the idea of starting a magazine of his own as the most hopeful way of living by his work, but he had no capital, and was obliged to abandon the project, and return to New York and miscellaneous journalism. To add to his troubles his wife, a cousin of his own, whom he had married in 1836, and to whom he was passionately attached, was in very delicate health, and during a lingering illness of eight years gave him constant anxiety. We have only to look at the character of Poe's work, and the condition of such literature commercially, to see why it was that the most popular writer of his generation in America had to struggle so hard for a bare subsistence. His short stories were an easy prey for the newspaper pirate, and when thousands were reading them the author received nothing but the few dollars paid him by the publication in which they first appeared. The *Raven* was published first in 1845, and in a few months was being read and recited and parodied wherever the English language was spoken; but the half-starved poet, who had to live by his genius, received only two pounds for the production. And, fertile and active as his imagination was, these short works of his, which served for the passing sensation of the newspaper reader, were far from being extempore effusions. His *Philosophy of Composition* is sometimes, indeed generally, regarded as half-serious half a jest in the author's peculiar way of mystification. But to any one who examines Poe's work closely by the light of this essay it is obvious that the disclosure of his method is only too seriously true. It would have been well for his own powers of endurance if he had composed on a less exacting and exhausting system. The most fantastic of Poe's creations are not the product of the imagination abandoned to the impulses of a dominant mood; the effects are deliberately calculated, as he says they were, step by step and point by point to a prearranged culmination. A man writing on such a system, with the wolf at the door and affections daily on the rack, could hardly have endured the strain if he had had a constitution of iron. It was no wonder that Poe's health became disordered, or that, during the last years of his wife's illness and the two remaining years through which he survived her, he had recourse to the dangerous help of stimulants. Not only did he subject his imagination to exhausting condition, but he wasted his force in doing with superfluous thoroughness what a ready journalist would have dismissed with a few easy sentences of commonplace. When we read his criticisms, which are full of insight and suggestion, we see that in reviewing a book or a poem he was never satisfied till he had thought out what could be done

with the subject. His famous feat in anticipating the plot of *Barnaby Rudge* from the opening chapters was only a sample of the thoroughness with which he threw himself into whatever he undertook. Poe failed to make a living by literature, not because he was an irregular profligate in the vulgar sense, but because he did ten times as much work as he was paid to do—a species of profligacy, perhaps, but not quite the same in kind as that with which he was charged by his malignant biographer.

The current story about his breaking off his engagement with Mrs Whitman by presenting himself at her house in a state of violent drunkenness has been proved to be a fabrication, and many other stories about him have been exploded by Mr Ingram. His wife died in 1847, and he followed her in 1849, dying under painful circumstances at Baltimore. For a critical estimate of Poe's writings the reader may be referred to Professor Nichol's *American Literature*. There are few English writers of this century whose fame is likely to be more enduring. The feelings to which he appeals are simple but universal, and he appeals to them with a force that has never been surpassed. (W. M.)

POERIO, CARLO (1803–1867), Italian statesman, born in 1803, was descended from an old Calabrian family and was the son of Giuseppe Poerio, a distinguished lawyer of Naples. In 1815 he accompanied his father into political exile, but, a pardon having been obtained in 1818, he returned to Naples where he afterwards adopted the profession of advocate. From 1837 to 1848 he was frequently arrested and imprisoned, but, when Ferdinand, moved by the demonstration of 27th January of the latter year, promulgated a constitution, he was at once raised to honour, being made prefect of police and shortly afterwards minister of public instruction. Discovering, however, that the king was only temporizing, he resigned office in April of the same year and was returned for Naples to parliament, where he led the constitutional opposition. On 19th July 1849 he was arrested, and after trial on the charge of belonging to the sect denominated the "Italian Unity," was condemned to irons. Chained in pairs, he and other fifteen political prisoners were confined in one small room in the bagno of Nisida near the lazaretto. The eloquent exposure of the horrors of the Neapolitan dungeons by Mr Gladstone in 1851, who emphasized especially the case of Poerio, awakened the universal indignation of Europe, but he did not obtain his liberty till 1858. He and other exiles were then placed on board a ship bound for the United States, but they compelled the crew to land them at Cork, whence Poerio made his way to London. In the following year he returned to Italy, and in 1860 he was elected deputy to the parliament of Turin, of which he was chosen vice-president in 1861. He died at Florence, 28th April 1867.

## P O E T R Y

Poetry  
as an  
energy  
and as  
an art.

IN modern criticism the word poetry is used sometimes to denote any expression (artistic or other) of imaginative feeling, sometimes to designate one of the fine arts.

As an expression of imaginative feeling, as the movement of an energy, as one of those great primal human forces which go to the development of the race, poetry in a wider sense has played as important a part as science.

In literatures (such as that of England) poetic art is found in others (such as that of Rome) poetic art is

the dominant quality. It is the same with individual writers. In classical literature Pindar may perhaps be taken as a type of the poets of energy; Virgil of the poets of art. With all his wealth of poetic art Pindar's mastery over symmetrical methods never taught him to "sow with the hand," as Corinna declared, while his poetic energy always impelled him to "sow with the whole sack." In English poetical literature Elizabeth Barrett Browning typifies, perhaps, the poets of energy; while Keats (not-

withstanding all his unquestionable inspiration) is mostly taken as a type of the poets of art. In French literature Hugo, notwithstanding all his mastery over poetic methods, represents the poets of energy.

In some writers, and these the very greatest—in Homer, Æschylus, Sophocles, Dante, Shakespeare, Milton, and perhaps Goethe—poetic energy and poetic art are seen in something like equipoise. It is of poetry as an art, however, that we have mainly to speak here; and all we have to say upon poetry as an energy is that the critic who, like Aristotle, takes this wide view of poetry—the critic who, like him, recognizes the importance of poetry in its relations to man's other expressions of spiritual force, claims a place in point of true critical sagacity above that of a critic who, like Plato, fails to recognize that importance. And assuredly no philosophy of history can be other than inadequate should it ignore the fact that poetry has had as much effect upon human destiny as that other great human energy by aid of which, from the discovery of the use of fire to that of the electric light, the useful arts have been developed.

With regard to poetry as an art, in the present work most of the great poems of the world have been or will be examined either in connexion with the names of the writers or with the various literatures to which they belong; consequently these remarks must be confined to general principles. To treat historically so vast a subject as poetry would be obviously impossible here.

Divisions  
of the  
subject.

All that can be attempted is to inquire briefly—(1) What is poetry? (2) What is the position it takes up in relation to the other arts? (3) What is its value and degree of expressional power in relation to these? and, finally, (4) What varieties of poetic art are the outcome of the two great kinds of poetic impulse, dramatic imagination and lyric or egoistic imagination?

What is  
poetry?

1. *What is Poetry?*—Definitions are for the most part alike unsatisfactory and treacherous; but definitions of poetry are proverbially so. Is it possible to lay down invariable principles of poetry, such as those famous "invariable principles" of the Rev. Mr Bowles, which in the earlier part of the century awoke the admiration of Southey and the wrath of Byron? Is it possible for a critic to say of any metrical phrase, stanza, or verse, "This is poetry," or "This is not poetry"? Can he, with anything like the authority with which the man of science pronounces upon the natural objects brought before him, pronounce upon the qualities of a poem? These are questions that have engaged the attention of critics ever since the time of Aristotle.

Byron, in his rough and ready way, has answered them in one of those letters to the late John Murray, which, rich as they are in nonsense, are almost as rich in sense. "So far are principles of poetry from being invariable," says he, "that they never were nor ever will be settled. These principles mean nothing more than the predilections of a particular age, and every age has its own and a different from its predecessor. It is now Homer and now Virgil; once Dryden and since Sir Walter Scott; now Corneille and now Racine; now Cr billon and now Voltaire." This is putting the case very strongly—perhaps too strongly. But if we remember that Sophocles lost the first prize for the * dipus Tyrannus*; if we remember what in Dante's time (owing partly, no doubt, to the universal ignorance of Greek) were the relative positions of Homer and Virgil, what in the time of Milton were the relative positions of Milton himself, of Shakespeare, and of Beaumont and Fletcher; again, if we remember Jeffrey's famous classification of the poets of his day, we shall be driven to pause over Byron's words before dismissing them. Yet some definition, for the purpose of this essay,

must be here attempted; and, using the phrase "absolute poetry" as the musical critics use the phrase "absolute music," we may, perhaps, without too great presumption submit the following:—

*Absolute poetry is the concrete and artistic expression of the human mind in emotional and rhythmical language.* Absolute poetry defined.

This at least will be granted, that no literary expression can properly speaking be called poetry that is not in a certain deep sense emotional, whatever may be its subject matter, concrete in its method and its diction, rhythmical in movement, and artistic in form.

That the expression of all real poetry must be concrete in method and diction is obvious, and yet this dictum would exclude from the definition much of what is called didactic poetry. With abstractions the poet has nothing to do, save to take them and turn them into concretions; for, as artist, he is simply the man who by instinct embodies in concrete forms that "universal idea" which Gravina speaks of—that which is essential and elemental in nature and in man; as poetic artist he is simply the man who by instinct chooses for his concrete forms metrical language. And the questions to be asked concerning any work of art are simply these—

Is that which is here embodied really permanent, universal, and elemental? and Is the concrete form embodying it really beautiful—acknowledged as beautiful by the soul of man in its highest moods? Any other question is an impertinence.

Examples are always useful in discussions such as this.

As an example of the absence of concrete form in verse take the following lines from George Eliot's *Spanish Gypsy*:—

"Speech is but broken light upon the depth  
Of the unspoken; even your loved words  
Float in the larger meaning of your voice  
As something dimmer."

Without discussing the question of blank verse cadence and the weakness of a line where the main accent falls upon a positive hiatus, "of the unspoken," we would point out that this powerful passage shows the spirit of poetry without its concrete form. The abstract method is substituted for the concrete. Such an abstract phrase as "the unspoken" belongs entirely to prose.

As to what is called ratiocinative poetry, it might perhaps be shown that it does not exist at all. Not by syllogism, but *per saltum*, must the poet reach in every case his conclusions. We listen to the poet—we allow him to address us in rhythm or in rhyme—we allow him to sing to us while other men are only allowed to talk, not because he argues more logically than they, but because he feels more deeply and perhaps more truly. It is for his listeners to be knowing and ratiocinative; it is for him to be gnomic and divinely wise.

That poetry must be metrical or even rhythmical in movement, however, is what some have denied. Here we touch at once the very root of the subject. The difference between all literature and mere "word-kneading" is that, while literature is alive, word-kneading is without life. This literary life, while it is only bipartite in prose, seems to be tripartite in poetry; that is to say, while prose requires intellectual life and emotional life, poetry seems to require not only intellectual life and emotional life but rhythmic life, this last being the most important of all according to many critics, though Aristotle is not among these. Here indeed is the "fork" between the old critics and the new. Unless the rhythm of any metrical passage is so vigorous, so natural, and so free that it seems as though it could live, if need were, by its rhythm alone, has that passage any right to exist? and should it not, if the substance is good, be forthwith

demetricized and turned into prose! Thoreau has affirmed that prose, at its best, has high qualities of its own beyond the ken of poetry; to compensate for the sacrifice of these, should not the metrical gains of any passage be beyond all cost?

Import-  
ance of  
metrical  
ques-  
tions

But this argument might be pressed further still. It might seem bold to assert that, in many cases, the mental value of poetry may actually depend upon form and colour, but would it not be true? The mental value of poetry must be judged by a standard not applicable to prose; but, even with regard to the different kinds of poetry, we must not compare poetry whose mental value consists in a distinct and logical enunciation of ideas, such as that of Lucretius and Wordsworth, and poetry whose mental value consists partly in the suggestive richness of passion or symbol latent in rhythm (such as that of Sappho sometimes, Pindar often, Shelley always), or latent in colour, such as that of some of the Persian poets. To discuss the question, Which of these two kinds of poetry is the more precious? would be idle, but are we not driven to admit that certain poems whose strength is rhythm, and certain other poems whose strength is colour, while devoid of any logical statement of thought, may be as fruitful of thoughts and emotions too deep for words as a shaken prism is fruitful of tinted lights? The mental forces at work in the production of a poem like the *Excursion* are of a very different kind from the mental forces at work in the production of a poem like Shelley's "Ode to the West Wind." In the one case the poet's artistic methods, like those of the Greek architect, show, and are intended to show, the solid strength of the structure. In the other, the poet's artistic methods, like those of the Arabian architect, contradict the idea of solid strength—make the structure appear to hang over our heads like the cloud pageantry of heaven. But, in both cases, the solid strength is, and must be, there, at the base. Before the poet begins to write he should ask himself which of these artistic methods is natural to him; he should ask himself whether his natural impulse is towards the weighty iambic movement whose primary function is to state, or towards those lighter movements which we still call, for want of more convenient words, anapestic and dactylic, whose primary function is to suggest. Whenever Wordsworth and Keats pass from the former to the latter they pass at once into doggerel. Nor is it difficult to see why English anapestic and dactylic verse must suggest and not state, as even so comparatively successful a *tour de force* as Shelley's "Sensitive Plant" shows. Conciseness is a primary virtue of all statement. The moment the English poet tries to "pack" his anapestic or dactylic line, as he can pack his iambic line, his versification becomes rugged, harsh, pebbly—becomes so of necessity. Nor is this all: anapestic and dactylic verse must in English be obtrusively alliterative, or the same pebbly effect begins to be felt. The anapestic line is so full of syllables that in a language where the consonants dominate the vowels (as in English), these syllables grate against each other, unless their corners are artfully bevelled by one of the only two *smoothing* processes at the command of an English versifier—obtrusive alliteration, or an obtrusive use of liquids. Now these demands of form may be turned by the perfect artist to good account if his appeal to the listener's soul is primarily that of suggestion by sound or symbol, but if his appeal is that of direct and logical statement the diffuseness inseparable from good anapestic and dactylic verse is a source of weakness such as the true artist should find intolerable.

But enough has been said to show that in discussing poetry questions of versification touch, as we have said, the very root of the subject.

Using the word "form" in a wider sense still, a sense it is that includes "composition," it can be shown that poetry to be entitled to the name must be artistic in form. Whether a poem be a Welsh *trïan* or a *stornello* improvised by an Italian peasant girl, whether it be an ode by Keats or a tragedy by Sophocles, it is equally a work of art. The artist's command over form may be shown in the peasant girl's power of spontaneously rendering in simple verse, in her *stornello* or *rispetto*, her emotions through nature's symbols; it may be shown by Keats in that perfect fusion of all poetic elements of which he was such a master, in the manipulation of language so beautiful both for form and colour that thought and words seem but one blended loveliness; or it may be shown by Sophocles in a mastery over what in painting is called composition, in the exercise of that wise vision of the artist which, looking before and after, sees the thing of beauty as a whole, and enables him to grasp the eternal laws of cause and effect in art and bend them to his own wizard will. In every case, indeed, form is an essential part of poetry; and, although George Sand's saying that "L'art est une forme" applies perhaps more strictly to the plastic arts (where the soul is reached partly through mechanical means), its application to poetry can hardly be exaggerated.

Owing, however, to the fact that the word *ποίησις* (first used to designate the poetic artist by Herodotus) means maker, Aristotle seems to have assumed that the indispensable basis of poetry is invention. He appears to have thought that a poet is a poet more on account of the composition of the action than on account of the composition of his verses. Indeed he said as much as this. Of epic poetry he declared emphatically that it produces its imitations either by mere articulate words or by metre super-added. This is to widen the definition of poetry so as to include all imaginative literature, and Plato seems to have given an equally wide meaning to the word *ποίησις*. Only, while Aristotle considered *ποίησις* to be an imitation of the facts of nature, Plato considered it to be an imitation of the dreams of man. Aristotle ignored, and Plato slighted, the importance of versification (though Plato on one occasion admitted that he who did not know rhythm could be called neither musician nor poet). It is impossible to discuss here the question whether an imaginative work in which the method is entirely concrete and the expression entirely emotional, while the form is unmetrical, is or is not entitled to be called a poem. That there may be a kind of unmetrical narrative so poetic in motive, so concrete in diction, so emotional in treatment, as to escape altogether from those critical canons usually applied to prose, we shall see when, in discussing the epic, we come to touch upon the Northern sagas.

Perhaps the first critic who tacitly revolted against the dictum that substance, and not form, is the indispensable basis of poetry was Dionysius of Halicarnassus, whose treatise upon the arrangement of words is really a very fine piece of literary criticism. In his acute remarks upon the arrangement of the words in the sixteenth book of the *Odyssey*, as compared with that in the story of Gyges by Herodotus, was perhaps first enunciated clearly the doctrine that poetry is fundamentally a matter of style. The Aristotelian theory as to invention, however, dominated all criticism after as well as before Dionysius. When Bacon came to discuss the subject (and afterwards) the only division between the poetical critics was perhaps between the followers of Aristotle and those of Plato as to what poetry should, and what it should not, imitate. It is curious to speculate as to what would have been the result had the poets followed the critics in this matter. Had not the instinct of the poet been too strong for the schools, would poetry as an art have been lost and merged in such imagina-

tive prose as Plato's? Or is not the instinct for form too strong to be stilled? By the poets themselves metre was always considered to be the one indispensable requisite of a poem, though, as regards criticism, so recently as the time of the appearance of the *Waverley Novels*, the *Quarterly Review* would sometimes speak of them as "poems"; and perhaps even now there are critics of a very high rank who would do the same with regard to romances so concrete in method and diction, and so full of poetic energy, as *Wuthering Heights* and *Jane Eyre*, where we get absolutely all that Aristotle requires for a poem. On the whole, however, the theory that versification is not an indispensable requisite of a poem seems to have become nearly obsolete in our time. Perhaps, indeed, many critics would now go so far in the contrary direction as to say with Hegel (*Ästhetik*, iii. p. 289) that "metre is the first and only condition absolutely demanded by poetry, yea even more necessary than a figurative picturesque diction." At all events this at least may be said that in our own time the division between poetical critics is not between Aristotelians and Baconians; it is now of a different kind altogether. While one group of critics may still perhaps say with Dryden that "a poet is a maker, as the name signifies," and that "he who cannot make, that is, invent, has his name for nothing," another group contends that it is not the invention but the artistic treatment, the form, which determines whether an imaginative writer is a poet or a writer of prose,—contends, in short, that emotion is the basis of all true poetic expression, whatever be the subject matter, that thoughts must be expressed in an emotional manner before they can be brought into poetry, and that this emotive expression demands even yet something else, viz., style and form.

The poetic atmosphere.

But, although many critics are now agreed that "L'art est une forme," that without metre and without form there can be no poetry, there are few who would contend that poetry can exist by virtue of any one of these alone, or even by virtue of all these combined. Quite independent of verbal melody, though mostly accompanying it, and quite independent of "composition," there is an atmosphere floating around the poet through which he sees everything, an atmosphere which stamps his utterances as poetry; for instance, among all the versifiers contemporary with Donne there was none so rugged as he occasionally was, and yet such songs as "Sweetest love, I do not go for weariness of thee" prove how true a poet he was whenever he could master those technicalities which far inferior poets find comparatively easy. While rhythm may to a very considerable degree be acquired (though, of course, the highest rhythmical effects never can), the power of looking at the world through the atmosphere that floats before the poet's eyes is not to be learned and not to be taught. This atmosphere is what we call *poetic imagination*, a subject which will have to be fully discussed further on. But first it seems necessary to say a word or two upon that high temper of the soul which in truly great poetry gives birth to this poetic imagination.

The poetic temper.

The "message" of poetry must be more unequivocal, more thoroughly accentuated, than that of any of the other fine arts. With regard to modern poetry, indeed, it may almost be said that if any writer's verse embodies a message, true, direct, and pathetic, we in modern Europe cannot stay to inquire too curiously about the degree of artistic perfection with which it is delivered, for Wordsworth's saying "That which comes from the heart goes to the heart" applies very closely indeed to modern poetry. The most truly passionate poet in Greece was no doubt in a deep sense the most artistic poet; but in her case art and passion were one, and that is why she has been so cruelly misunderstood. The most truly passionate nature,

and perhaps the greatest soul, that in our time has expressed itself in English verse is Elizabeth Barrett Browning; at least it is certain that, with the single exception of Hood in the "Song of the Shirt," no writer of the century has really touched our hearts with a hand so powerful as hers,—and this notwithstanding violations of poetic form, notwithstanding defective rhymes, such as would appal some of the contemporary versifiers of England and France "who lisp in numbers for the numbers [and nothing else] come." The truth is that in order to produce poetry the soul must for the time being have reached that state of exaltation, that state of freedom from self-consciousness, depicted in the lines—

"I started once, or seemed to start, in pain,  
Resolved on noble things, and strove to speak,  
As when a great thought strikes along the brain,  
And flushes all the cheek."

Whatsoever may be the poet's "knowledge of his art," into this mood he must always pass before he can write a truly poetic line. For, notwithstanding all that we have said and are going to say upon poetry as a fine art, it is in the deepest sense of the word an "inspiration" indeed. No man can write a line of genuine poetry without having been "born again" (or, as the true rendering of the text says, "born from above"); and then the mastery over those highest reaches of form which are beyond the ken of the mere versifier comes to him as a result of the change. Hence, with all Mrs Browning's metrical blemishes, the splendour of her metrical triumphs at her best.

For what is the deep distinction between poet and prose-man? A writer may be many things besides a poet; he may be a warrior like Æschylus, a man of business like Shakespeare, a courtier like Chaucer, or a cosmopolitan philosopher like Goethe; but the moment the poetic mood is upon him all the trappings of the world with which for years he may perhaps have been clothing his soul—the world's knowingness, its cynicism, its self-seeking, its ambition—fall away, and the man becomes an inspired child again, with ears attuned to nothing but the whispers of those spirits from the Golden Age, who, according to Hesiod, haunt and bless the degenerate earth. What such a man produces may greatly delight and astonish his readers, yet not so greatly as it delights and astonishes himself. His passages of pathos draw no tears so deep or so sweet as those that fall from his own eyes while he writes; his sublime passages overawe no soul so imperiously as his own; his humour draws no laughter so rich or so deep as that stirred within his own breast.

It might almost be said, indeed, that Sincerity and Conscience, the two angels that bring to the poet the wonders of the poetic dream, bring him also the deepest, truest delight of form. It might almost be said that by aid of sincerity and conscience the poet is enabled to see more clearly than other men the eternal limits of his own art—to see with Sophocles that nothing, not even poetry itself, is of any worth to man, invested as he is by the whole army of evil, unless it is in the deepest and highest sense good, unless it comes linking us all together by closer bonds of sympathy and pity, strengthening us to fight the foes with whom fate and even nature, the mother who bore us, sometimes seem in league—to see with Milton that the high quality of man's soul which in English is expressed by the word virtue is greater than even the great poem he prized, greater than all the rhythms of all the tongues that have been spoken since Babel—and to see with Shakespeare and with Shelley that the high passion which in English is called love is lovelier than all art, lovelier than all the marble Mercuries that "await the chisel of the sculptor" in all the marble hills. So much for our first inquiry—"What is poetry?"

Sincerity and conscience.

The position of poetry in relation to the other arts.

2. *What Position does Poetry take up in Relation to the other Arts?*—Notwithstanding the labours of Lessing and his followers, the position accorded by criticism to poetry in relation to the other arts was never so uncertain and anomalous as at the present moment. On the one hand there is a class of critics who, judging from their perpetual comparison of poems to pictures, claim her as a sort of handmaid of painting and sculpture. On the other hand the disciples of Wagner, while professing to do homage to poetry, claim her as the handmaid of music. To find her proper place is therefore the most important task the critic can undertake at this time, though it is one far beyond the scope of a paper so brief as this. With regard to the relations of poetry to painting and sculpture, however, it seems necessary to glance for a moment at the saying of Simonides, as recorded by Plutarch, that poetry is a speaking picture and that painting is a mute poetry. It appears to have had upon modern criticism as much influence since the publication of Lessing's *Lacoon* as it had before. Perhaps it is in some measure answerable for the modern vice of excessive word-painting. Beyond this one saying, there is little or nothing in Greek literature to show that the Greeks recognized between poetry and the plastic and pictorial arts an affinity closer than that which exists between poetry and music and dancing. Understanding artistic methods more profoundly than the moderns, and far too profoundly to suppose that there is any special and peculiar affinity between an art whose medium of expression is marble and an art whose medium of expression is a growth of oral symbols, the Greeks seem to have studied poetry not so much in its relation to painting and sculpture as in its relation to music and dancing. It is matter of familiar knowledge, for instance, that at the Dionysian festival it was to the poet as "teacher of the chorus" (*χοροδιδάσκαλος*) that the prize was awarded, even though the "teacher of the chorus" were *Æschylus* himself or *Sophocles*. And this recognition of the relation of poetry to music is perhaps one of the many causes of the superiority of Greek to all other poetry in adapting artistic means to artistic ends. In Greek poetry, even in Homer's description of the shield of Achilles, even in the famous description by *Sophocles* of his native woods in the *Edipus Coloneus*, such word-painting as occurs seems, if not inevitable and unconscious, so alive with imaginative feeling as to become part and parcel of the dramatic or lyric movement itself. And whenever description is so introduced the reader of Greek poetry need not be told that the scenery itself rises before the listener's imagination with a clearness of outline and a vigour of colour such as no amount of detailed word-painting in the modern fashion can achieve. The picture even in the glorious verses at the end of the eighth book of the *Iliad* rises before our eyes—seems actually to act upon our bodily senses—simply because the poet's eagerness to use the picture for merely illustrating the solemnity and importance of his story lends to the picture that very authenticity which the work of the modern word-painter lacks.

Relation of poetry to music.

That the true place of poetry lies between music on the one hand and prose, or loosened speech, on the other, was, we say, taken for granted by the one people in whom the artistic instinct was fully developed.

No doubt they used the word music in a very wide sense, in a sense that might include several arts. But it is a suggestive fact that, in the Greek language, long before poetic art was called "making" it was called "singing." The poet was not ποιητής but ἀοιδός. And as regards the Romans it is curious to see how every now and then the old idea that poetry is singing rather than making will disclose itself. It will be remembered for instance how Terence, in the prologue of *Phormio*, alludes

to poets as musicians. That the ancients were right in this we should be able to show did our scheme permit an historical treatment of poetry: we should be able to show that music and the lyrical function of the poet began together, but that here, as in other things, the progress of art from the implicit to the explicit has separated the two. Every art has its special function, has a certain work which it can do better than any one of its sister arts. Hence its right of existence. For instance, before the "sea of emotion" within the soul has become "curdled into thoughts," it can be expressed in inarticulate tone. Hence, among the fine arts, music is specially adapted for rendering it. It was perhaps a perception of this fact which made the Syrian Gnostics define life to be "moving music." When this sea of emotion has "curdled into thoughts," articulate language rhythmically arranged—words steeped in music and colour, but at the same time embodying ideas—can do what no mere wordless music is able to achieve in giving it expression, just as unrhythmical language, language mortised in a foundation of logic, that is to say prose, can best express these ideas as soon as they have cooled and settled and cleared themselves of emotion altogether. Yet every art can in some degree invade the domain of her sisters, and the nearer these sisters stand to each other the more easily and completely can this invasion be accomplished. Prose, for instance, can sometimes, as in the case of Plato, do some of the work of poetry (however imperfectly, and however trammelled by heavy conditions); and sometimes poetry, as in Pindar's odes and the waves of the Greek chorus, can do, though in the same imperfect way, the work of music. The poems of Sappho, however, are perhaps the best case in point. Here the poet's passion is expressed so completely by the mere sound of her verses that a good recitation of them to a person ignorant of Greek would convey something of that passion to the listener; and similar examples almost as felicitous might be culled from Homer, from *Æschylus*, and from *Sophocles*. Nor is this power confined to the Greek poets. The students of Virgil have often and with justice commented on such lines as *Æn.* v. 481 (where the sudden sinking of a stricken ox is rendered by means of rhythm), and such lines as *Georg.* ii. 441, where, by means of verbal sounds, the gusts of wind about a tree are rendered as completely as though the voice were that of the wind itself. In the case of Sappho the effect is produced by the intensity of her passion, in the case of Homer by the intensity of the dramatic vision, in the case of Virgil by a supreme poetic art. But it can also be produced by the mere ingenuity of the artist, as in Edgar Poe's "Ulalume." The poet's object in that remarkable *tour de force* was to express dull and hopeless gloom in the same way that the mere musician would have expressed it,—that is to say, by monotonous reiterations, by hollow and dreadful reverberations of gloomy sounds—though as an artist whose vehicle was articulate speech he was obliged to add gloomy ideas, in order to give to his work the intellectual coherence necessary for its existence as a poem. He evidently set out to do this, and he did it, and "Ulalume" properly intoned would produce something like the same effect upon a listener knowing no word of English that it produces upon us.

On the other hand, music can trench very far upon the domain of articulate speech, as we perceive in the wonderful instrumentation of Wagner. Yet, while it can be shown that the place of poetry is scarcely so close to sculpture and painting as to music on the one side and loosened speech on the other, the affinity of poetry to music must not be exaggerated. We must be cautious how we follow the canons of Wagner and the more enthusiastic of his disciples, who almost seem to think that

inarticulate tone can not only suggest ideas but express them—can give voice to the *Verstand*, in short, as well as to the *Vernunft* of man. Even the Greeks drew a fundamental distinction between melic poetry (poetry written to be sung) and poetry that was written to be recited. It is a pity that, while modern critics of poetry have understood or at least have given attention to painting and sculpture, so few have possessed any knowledge of music—a fact which makes Dante's treatise *De Vulgari Eloquentia* so important. Dante was a musician, and seems to have had a considerable knowledge of the relations between musical and metrical laws. But he did not, we think, assume that these laws are identical.

If it is indeed possible to establish the identity of musical and metrical laws, it can only be done by a purely scientific investigation; it can only be done by a most searching inquiry into the subtle relations that we know must exist throughout the universe between all the laws of undulation. And it is curious to remember that some of the greatest masters of verbal melody have had no knowledge of music, while some have not even shown any love of it. All Greek boys were taught music, but whether Pindar's unusual musical skill was born of natural instinct and inevitable passion, or came from the accidental circumstance that his father was, as has been alleged, a musician, and that he was as a boy elaborately taught musical science by Lasus of Hermione, we have no means of knowing. Nor can we now learn how much of Milton's musical knowledge resulted from a like exceptional "environment," or from the fact that his father was a musician. But when we find that Shelley seems to have been without the real passion for music, that Rossetti disliked it, and that Coleridge's apprehension of musical effects was of the ordinary nebulous kind, we must hesitate before accepting the theory of Wagner.

The question cannot be pursued here; but if it should on inquiry be found that, although poetry is more closely related to music than to any of the other arts, yet the power over verbal melody at its very highest is so all-sufficing to its possessor as in the case of Shelley and Coleridge that absolute music becomes a superfluity, this would only be another illustration of that intense egoism and concentration of force—the impulse of all high artistic energy—which is required in order to achieve the rarest miracles of art.

Relation of poetry to prose. With regard to the relation of poetry to prose, Coleridge once asserted in conversation that the real antithesis of poetry was not prose but science. And if he was right the difference in kind lies, not between the poet and the prose writer, but between the literary artist (the man whose instinct is to manipulate language) and the man of facts and of action whose instinct impels him to act, or, if not to act, to inquire.

One thing is at least certain, that prose, however fervid and emotional it may become, must always be directed, or seem to be directed, by the reins of logic. Or, to vary the metaphor, like a captive balloon it can never really leave the earth.

Indeed, with the literature of knowledge as opposed to the literature of power poetry has nothing to do. Facts have no place in poetry until they are brought into relation with the human soul. But a mere catalogue of ships may become poetical if it tends to show the strength and pride and glory of the warriors who invested Troy; a detailed description of the designs upon a shield, however beautiful and poetical in itself, becomes still more so if it tends to show the skill of the divine artificer and the invincible splendour of a hero like Achilles. But mere dry exactitude of imitation is not for poetry but for loosened speech. Hence, most of the so-called poetry of Hesiod is not poetry

at all. The Muses who spoke to him about "truth" on Mount Helicon made the common mistake of confounding fact with truth. And here we touch upon a very important matter. The reason why in prose speech is loosened is that, untrammelled by the laws of metre, language is able with more exactitude to imitate nature, though of course speech, even when "loosened," cannot, when actual sensible objects are to be depicted, compete in any real degree with the plastic arts in accuracy of imitation, for the simple reason that its media are not colours nor solids but symbols—arbitrary symbols which can be made to indicate, but never to reproduce, colours and solids. Accuracy of imitation is the first requisite of prose. But the moment language has to be governed by the laws of metre—the moment the conflict begins between the claims of verbal music and the claims of colour and form—then prosaic accuracy has to yield; sharpness of outline, mere fidelity of imitation, such as is within the compass of prose, have in some degree to be sacrificed. But, just as with regard to the relations between poetry and music the greatest master is he who borrows the most that can be borrowed from music, and loses the least that can be lost from metre, so with regard to the relations between poetry and prose the greatest master is he who borrows the most that can be borrowed from prose and loses the least that can be lost from verse. No doubt this is what every poet tries to do by instinct; but some sacrifice on either side there must be, and, with regard to poetry and prose, modern poets at least might be divided into those who make picturesqueness yield to verbal melody, and those who make verbal melody yield to picturesqueness.

With one class of poets, fine as is perhaps the melody, it is made subservient to outline or to colour; with the other class colour and outline both yield to metre. The chief aim of the first class is to paint a picture; the chief aim of the second is to sing a song. Weber, in driving through a beautiful country, could only enjoy its beauty by translating it into music. The same may be said of some poets with regard to verbal melody. The supreme artist, however, is he whose pictorial and musical power are so interfused that each seems born of the other, as is the case with Sappho, Homer, Æschylus, Sophocles, and indeed most of the great Greek poets. Among our own poets (leaving the two supreme masters undiscussed) Keats and Coleridge have certainly done this. The colour seems born of the music and the music born of the colour. In French poetry the same triumph has been achieved in Victor Hugo's magnificent poem "En Marchant la Nuit dans un Bois," which, as a rendering through verbal music of the witchery of nature, stands alone in the poetry of France. For there the poet conquers that crowning difficulty we have been alluding to, the difficulty of stealing from prose as much distinctness of colour and clearness of outline as can be imported into verse with as little sacrifice as possible of melody.

But to return to the general relations of poetry to prose. If poetry can in some degree invade the domain of prose, so on the other hand prose can at times invade the domain of poetry, and no doubt the prose of Plato—what is called poetical prose—is a legitimate form of art. Poetry, the earliest form of literature, is also the final and ideal form of all pure literature; and, when Landor insists that poetry and poetical prose are antagonistic, we must remember that Landor's judgments are mostly based on feeling, and that his hatred of Plato would be quite sufficient basis with him for an entire system of criticism upon poetical prose. As with Carlyle, there was a time in his life when Plato (who of course is the great figure standing between the two arts of metre and loosened speech) had serious thoughts of becoming a poet. And

perhaps, like Carlyle, having the good sense to see his true function, he himself desisted from writing, and strictly forbade other men to write, in verse. If we consider this, and if we consider that certain of the great English masters of poetic prose in the 17th century were as incapable of writing in metre as their followers Richter and Carlyle, we shall hardly escape the conclusion on the one hand that the faculty of writing poetry is quite another faculty than that of producing work in the arts most closely allied to it, music and prose, but that on the other hand there is nothing antagonistic between these faculties. So much for poetry's mere place among the other arts.

**Importance of Poetry in Relation to other Arts.**—As to the comparative importance and value of poetry among the other arts, this is a subject upon which much discussion, of a more or less idle kind, has been wasted. We do not feel called to dwell at any length upon it here. Yet a word or two upon the question is necessary in order that we may understand what is the scope and what are the limits of poetry with regard to the other arts, especially with regard to music and to prose.

Where poetry is inferior and where superior to music; There is one great point of superiority that musical art exhibits over metrical art. This consists, not in the capacity for melody, but in the capacity for harmony in the musician's sense. The finest music of Æschylus, of Pindar, of Shakespeare, of Milton, is after all only a succession of melodious notes, and, in endeavouring to catch the harmonic intent of strophe, antistrophe, and epode in the Greek chorus and in the true ode (that of Pindar), we can only succeed by pressing memory into our service. We have to recall by memory the waves that have gone before, and then to imagine their harmonic power in relation to the waves at present occupying the ear. Counterpoint, therefore, is not to be achieved by the metricist, even though he be Pindar himself; but in music this perfect ideal harmony was foreshadowed perhaps in the earliest writing. We know at least that as early as the 12th century counterpoint began to show a vigorous life, and the study of it is now a familiar branch of musical science. Now, inasmuch as "Nature's own hymn" is and must be the harmonic blending of apparently independent and apparently discordant notes, among the arts whose appeal is through the ear that which can achieve counterpoint must perhaps rank as a pure art above one which cannot achieve it. We are of course speaking here of metre only. We have not time to inquire whether the counterpoint of absolute poetry is the harmony underlying apparently discordant emotions—the emotion produced by a word being more persistent than the emotion produced by an inarticulate sound.

to prose; But if poetry falls behind music in rhythmic scope, it is capable of rendering emotion after emotion has become disintegrated into thoughts, and here, as we have seen, it enters into direct competition with the art of prose. It can use the emphasis of sound, not for its own sake merely, but to strengthen the emphasis of sense, and can thus give a fuller and more adequate expression to the soul of man than music at its highest can give. With regard to prose, no doubt such writing as Plato's description of the chariot of the soul, his description of the island of Atlantis, or of Er's visit to the place of departed souls, comes but a short way behind poetry in imaginative and even in rhythmic appeal. It is impossible, however, here to do more than touch upon the subject of the rhythm of prose in its relation to the rhythm of poetry; for in this matter the genius of each individual language has to be taken into account.

Perhaps it may be said that deeper than all the rhythms of art is that rhythm which art would fain catch, the rhythm of nature; for the rhythm of nature is the rhythm

of life itself. This rhythm can be caught by prose as well as by poetry, such prose, for instance, as that of the English Bible. Certainly the rhythm of verse at its highest, such, for instance, as that of Shakespeare's greatest writings, is nothing more and nothing less than the metre of that energy of the spirit which surges within the bosom of him who speaks, whether he speak in verse or in impassioned prose. Being rhythm, it is of course governed by law, but it is a law which transcends in subtlety the conscious art of the metricist, and is only caught by the poet in his most inspired moods, a law which, being part of nature's own sanctions, can of course never be formulated but only expressed, as it is expressed in the melody of the bird, in the inscrutable harmony of the entire bird-chorus of a thicket, in the whisper of the leaves of the tree, and in the song or wail of wind and sea. Now is not this rhythm of nature represented by that "sense rhythm" which prose can catch as well as poetry, that sense rhythm whose finest expressions are to be found in the Bible, Hebrew and English, and in the Biblical movements of the English Prayer Book, and in the dramatic prose of Shakespeare at its best? Whether it is caught by prose or by verse, one of the virtues of the rhythm of nature is that it is translatable. Hamlet's peroration about man and Raleigh's apostrophe to death are as translatable into other languages as are the Hebrew psalms, or as is Manu's magnificent passage about the singleness of man (we quote from memory):—

"Single is each man born into the world; single he dies; single he receives the reward of his good deeds, and single the punishment of his evil deeds. When he dies his body lies like a fallen tree upon the earth, but his virtue accompanies his soul. Wherefore let man harvest and garner virtue, so that he may have an inseparable companion in traversing that gloom which is so hard to be traversed."

Here the rhythm, being the inevitable movement of emotion and "sense," can be caught and translated by every literature under the sun. While, however, the great goal before the poet is to compel the listener to expect his caesuric effects, the great goal before the writer of poetic prose is in the very opposite direction; it is to make use of the concrete figures and impassioned diction of the poet, but at the same time to avoid the recognized and expected metrical bars upon which the poet depends. The moment the prose poet passes from the rhythm of prose to the rhythm of metre the apparent sincerity of his writing is destroyed.

And now how stands poetry with regard to the plastic arts? This is in truth a vast subject, and has given birth to an infinitude of eloquent criticism in the present century. It cannot be expected that we should be able to discuss it adequately here. Yet this, too, must be glanced at. On the one side poetry is inferior to the plastic arts; on another side it is superior to them.

As compared with sculpture and painting the great infirmity of poetry, as an "imitation" of nature, is of course that the medium is always and of necessity words—even when no words could, in the dramatic situation, have been spoken. It is not only Homer who is obliged sometimes to forget that passion when at white heat is never voluble, is scarcely even articulate; the dramatists also are obliged to forget that in love and in hate, at their tensest, words seem weak and foolish when compared with the silent and satisfying triumph and glory of deeds, such as the plastic arts can render. This becomes manifest enough when we compare the Niobe group or the Laocoon group, or the great dramatic paintings of the modern world, with even the finest efforts of dramatic poetry, such as the speech of Andromache to Hector, or the speech of Priam to Achilles, nay such as even the cries of Cassandra in the *Agamemnon*, or the wailings of Lear over the dead Cordelia. Even when writing the words uttered by Oedipus, as the terrible truth

breaks in upon his soul, Sophocles must have felt that, in the holiest chambers of sorrow and in the highest agonies of suffering reigns that awful silence which not poetry, but painting sometimes, and sculpture always, can render. What human sounds could render the agony of Niobe, or the agony of Laocoon, as we see them in the sculptor's rendering? Not articulate speech at all; not words but wails. It is the same with hate; it is the same with love. We are not speaking merely of the unpacking of the heart in which the angry warriors of the *Iliad* indulge. Even such subtle writing as that of Æschylus and Sophocles falls below the work of the painter. Hate, though voluble perhaps, as Clytemnestra's when hate is at that red-hot glow which the poet can render, changes in a moment whenever that redness has been fanned to hatred's own last complexion—whiteness as of iron at the melting-point,—when the heart has grown far too big to be "unpacked" at all, and even the bitter epigrams of hate's own rhetoric, though brief as the terrier's snap before he fleshes his teeth, or as the short snarl of the tigress as she springs before her cubs in danger, are all too slow and sluggish for a soul to which language at its tensest has become idle play. But this is just what cannot be rendered by an art whose medium consists solely of words.

It is in giving voice, not to emotion at its tensest, but to the variations of emotion, it is in expressing the countless shifting movements of the soul from passion to passion, that poetry shows in spite of all her infirmities her superiority to the plastic arts. *Hamlet* and the *Agamemnon*, the *Iliad* and the *Œdipus Tyrannus*, are adequate to the entire breadth and depth of man's soul.

**Poetic imagination.** *Poetic Imagination.*—We have now reached our last general inquiry—What varieties of poetic art are the outcome of the two kinds of poetic impulse, dramatic imagination and lyric or egoistic imagination? It would of course be impossible within the space at our command to examine fully the subject of poetic imagination. For in order to do so we should have to enter upon the vast question of the effect of artistic environment upon the development of man's poetic imagination; we should have to inquire how the instinctive methods of each poet and of each group of poets have been modified and often governed by the methods characteristic of their own time and country. We should have to inquire, for instance, how far such landscape as that of Sophocles in the *Œdipus Coloneus* and such landscape as that of Wordsworth depends upon difference of individual temperament, and how far upon difference of artistic environment. That, in any thorough and exhaustive discussion of poetic imagination, the question of artistic environment must be taken into account, the case of the *Iliad* is alone sufficient to show—a case that will at once occur to the reader. Ages before Phrynichus, ages before an acted drama was dreamed of, a dramatic poet of the first order arose, and, though he was obliged to express his splendid dramatic imagination through epic forms, he expressed it almost as fully as if he had inherited the method and the stage of Sophocles. And if Homer never lived at all, then an entire group of dramatic poets arose in remote times whose method was epic instead of dramatic simply because there was then no stage.

This, contrasted with the fact that in a single half-century the tragic art of Greece arose with Æschylus, culminated with Sophocles, and decayed with Euripides, and contrasted also with the fact that in England at one time, and in Spain at one time, almost the entire poetic imagination of the country found expression in the acted drama alone, is sufficient to show that a poet's artistic methods are very largely influenced by the artistic environments of his country and time. So vast a subject as this,

however, is, as we say, quite beyond the scope of any essay like this, and we can only point to the familiar instance of the troubadours and the trouvères and then pass on.

With the trouvère (the poet of the *langue d'oïl*), the story or situation is always the end of which the musical language is the means; with the troubadour (the poet of the *langue d'oc*), the form is so beloved, the musical language so entralling, that, however beautiful may be the story or situation, it is felt to be no more than the means to a more beloved and beautiful end. But then nature makes her own troubadours and her own trouvères irrespective of fashion and of time—irrespective of *langue d'oc* and *langue d'oïl*. And, in comparing the troubadours with the trouvères, this is what strikes us at once—there are certain troubadours who by temperament, by original endowment of nature, ought to have been trouvères, and there are certain trouvères who by temperament ought to have been troubadours. Surrounding conditions alone have made them what they are. There are those whose impulse (though writing in obedience to contemporary fashions lyrics in the *langue d'oc*) is manifestly to narrate, and there are those whose impulse (though writing in obedience to contemporary fashions *fabliaux* in the *langue d'oïl*) is simply to sing. In other words, there are those who, though writing after the fashion of their brother-troubadours, are more impressed with the romance and wonderfulness of the human life outside them than with the romance and wonderfulness of their own passions, and who delight in depicting the external world in any form that may be the popular form of their time; and there are those who, though writing after the fashion of their brother-trouvères, are far more occupied with the life within them than with that outer life which the taste of their time and country calls upon them to paint—born rhythmists who must sing, who translate everything external as well as internal into verbal melody. Of the former class Pierre Vidal, of the latter class the author of "*Le Lay de l'Oïselet*," may be taken as the respective types.

That the same forces are seen at work in all literatures few students of poetry will deny,—though in some poetical groups these forces are no doubt more potent than in others, as, for instance, with the great parable poets of Persia, in some of whom there is perpetually apparent a conflict between the dominance of the Oriental taste for allegory and subtle suggestion, as expressed in the Zoroastrian definition of poetry,—“apparent pictures of unapparent realities,”—and the opposite yearning to represent human life with the freshness and natural freedom characteristic of Western poetry.

Allowing, however, for all the potency of external influences, we shall not be wrong in saying that of poetic imagination there are two distinct kinds—(1) the kind of poetic imagination seen at its highest in Æschylus, Sophocles, Shakespeare, and Homer, and (2) the kind of poetic imagination seen at its highest in Pindar, Dante, and Milton, or else in Sappho, Heine, and Shelley. The former, being in its highest dramatic exercise unconditioned by the personal or lyrical impulse of the poet, might perhaps be called absolute dramatic vision; the latter, being more or less conditioned by the personal or lyrical impulse of the poet, might be called relative dramatic vision. It seems impossible to classify poets, or to classify the different varieties of poetry, without drawing some such distinction as this, whatever words of definition we may choose to adopt.

For the achievement of all pure lyric poetry, such as the ode, the song, the elegy, the idyl, the sonnet, the stornello, it is evident that the imaginative force we have called relative vision will suffice. And if we consider the matter thoroughly, in many other forms of poetic art—forms

which at first sight might seem to require absolute vision—we shall find nothing but relative vision at work.

Even in Dante, and even in Milton and Virgil, it might be difficult to trace the working of any other than relative vision. And as to the entire body of Asiatic poets it might perhaps be found (even in view of the Indian drama) that relative vision suffices to do all their work. Indeed the temper which produces true drama is, it might almost be said, a growth of the Western mind. For, unless it be Semitic as seen in the dramatic narratives of the Bible, or Chinese as seen in that remarkable prose story, *The Two Fair Cousins*, translated by Rémusat, absolute vision seems to have but small place in the literatures of Asia. The wonderfulness of the world and the romantic possibilities of fate, or circumstance, or chance—not the wonderfulness of the character to whom these possibilities befall—are ever present to the mind of the Asiatic poet. Even in so late a writer as the poet of the *Shāh Nāmah*, the hero Irij, the hero Zal, and the hero Zohreb are in character the same person, the virtuous young man who combines the courage of youth with the wisdom and forbearance of age. And, as regards the earlier poets of Asia, it was not till the shadowy demigods and heroes of the Asiatic races crossed the Caucasus, and breathed a more bracing air, that they became really individual characters. But among the many qualities of man's mind that were invigorated and rejuvenated by that great exodus from the dreamy plains of Asia is to be counted, above all others, his poetic imagination. The mere sense of wonder, which had formerly been an all-sufficing source of pleasure to him, was all-sufficing no longer. The wonderful adventure must now be connected with a real and interesting individual character. It was left for the poets of Europe to show that, given the interesting character, given the Achilles, the Odysseus, the Helen, the Priam, any adventure happening to such a character becomes interesting.

What then is this absolute vision, this true dramatic imagination which can hardly be found in Asia—which even in Europe cannot be found except in rare cases? Between relative and absolute vision the difference seems to be this, that the former only enables the poet, even in its very highest exercise, to make his own individuality, or else humanity as represented by his own individuality, live in the imagined situation; the latter enables him in its highest exercise to make special individual characters other than the poet's own live in the imagined situation.

"That which exists in nature," says Hegel, "is a something purely individual and particular. Art on the contrary is essentially destined to manifest the general." And no doubt this is true as regards the plastic arts, and true also as regards literary art, save in the very highest reaches of pure drama and pure lyric, when it seems to become art no longer—when it seems to become the very voice of Nature herself. The cry of Priam when he puts to his lips the hand that slew his son is not merely the cry of a bereaved and aged parent; it is the cry of the individual king of Troy, and expresses above everything else that most naïf, pathetic, and winsome character. Put the words into the mouth of the irascible and passionate Lear and they would be entirely out of keeping.

It may be said then that, while the poet of relative vision, even in its very highest exercise, can only, when depicting the external world, deal with the general, the poet of absolute vision can compete with Nature herself and deal with both general and particular. Now if this is really so we may perhaps find a basis for a classification of poetry and of poets. That all poets must be singers has already been maintained. But singers seem to be divisible into three classes:—first the pure lyrists, each

of whom can with his one voice sing only one tune; secondly the epic poets, save Homer, the bulk of the narrative poets, and the quasi-dramatists, each of whom can with his one voice sing several tunes; and thirdly the true dramatists, who, having, like the nightingale of Gongora, many tongues, can sing all tunes.

It is to the first-named of these classes that most poets belong. With regard to the second class, there are not of course many poets left for it: the first absorbs so many. But, when we come to consider that among those who, with each his one voice, can sing many tunes, are Pindar, Firdausi, Jami, Virgil, Dante, Milton, Spenser, Goethe, Byron, Coleridge, Shelley, Keats, Schiller, Victor Hugo, the second class is so various that no generalization save such a broad one as ours could embrace its members. And now we come to class three, and must pause. The third class is necessarily very small. In it can only be placed such names as Shakespeare, Æschylus, Sophocles, Homer, and (hardly) Chaucer.

These three kinds of poets represent three totally different kinds of poetic activity.

With regard to the first, the pure lyrists, the impulse is pure egoism. Many of them have less of even relative vision at its highest than the mass of mankind. They are often too much engaged with the emotions within to have any deep sympathy with the life around them. Of every poet of this class it may be said that his mind to him "a kingdom is," and that the smaller the poet the bigger to him is that kingdom. To make use of a homely image—like the chaffinch whose eyes have been pricked by the bird-fancier, the pure lyrist is sometimes a warbler because he is blind. Still he feels that the Muse loves him exceedingly. She takes away his eyesight, but she gives him sweet song. And his song is very sweet, very sad, and very beautiful; but it is all about the world within his own soul—its sorrows, joys, fears, and aspirations.

With regard to the second class the impulse here is no doubt a kind of egoism too; yet the poets of this class are all of a different temper from the pure lyrists. They have a wide imagination; but it is still relative, still egoistic. They have splendid eyes, but eyes that never get beyond seeing general, universal humanity (typified by themselves) in the imagined situation. Not even to these is it given to break through that law of centrality by which every "me" feels itself to be the central "me"—the only "me" of the universe, round which all other spurious "mes" revolve. This "me" of theirs they can transmute into many shapes, but they cannot create other "mes,"—nay, for egoism, some of them scarcely would perhaps if they could.

The third class, the true dramatists, whose impulse is the simple yearning to create akin to that which made "the great Vishnu yearn to create a world," are "of imagination all compact,"—so much so that when at work "the divinity" which Iamblichus speaks of "seizes for the time the soul and guides it as he will."

The distinction between the pure lyrists and the other two classes of poets is obvious enough. But the distinction between the quasi-dramatists and the pure dramatists requires a word of explanation before we proceed to touch upon the various kinds of poetry that spring from the exercise of relative and absolute vision. Sometimes, to be sure, the vision of the true dramatists—the greatest dramatists—will suddenly become narrowed and obscured, as in that part of the *Œdipus Tyrannus* where Sophocles makes Œdipus ignorant of what every one in Thebes must have known, the murder of Laius. And again, finely as Sophocles has conceived the character of Electra, he makes her, in her dispute with Chrysothemis, give expression to sentiments that, in another play of his own, come far more

Examples  
of relative  
vision.

appropriately from the lofty character of Antigone in a parallel dispute with Ismene. And, on the other hand, examples of relative vision, in its furthest reaches, can be found in abundance everywhere, especially in Virgil, Dante, Calderon, and Milton; but in our limited space we can give but two or three. Some of the most remarkable examples of that high kind of relative vision which may easily be mistaken for absolute vision may be found in those great prose epics of the North which Aristotle would have called poems. Here is one from the *Völsunga Saga*. While the brothers of Gudrun are about their treacherous business of murdering Sigurd, her husband, as he lies asleep in her arms, Brynhild, Sigurd's former love, who in the frenzy of "love turned to hate" has instigated the murderers to the deed, hovers outside the chamber with Gunnar, her husband, and listens to the wail of her rival who is weltering in Sigurd's blood. At the sound of that wail Brynhild laughs

"Then said Gunnar to her, Thou laughest not because thy heart  
rooms are gladdened, or else why dost thou things that are so vain?"

This is of course very fine; but, as any two characters in that dramatic situation might have done that dramatic business, fine as it is,—as the sagaman gives us the general and not the particular,—the vision at work is not absolute but relative at its very highest exercise. But our examples will be more interesting if taken from English poets. In Coleridge's "Ancient Mariner" we find an immense amount of relative vision of so high a kind that at first it seems absolute vision. When the ancient mariner, in his narrative to the wedding guest, reaches the slaying of the albatross, he stops, he can proceed no further, and the wedding guest exclaims—

"God save thee, Ancient Mariner,  
From the fiends that plague thee thus!  
Why look'st thou so?" "With my cross-bow  
I shot the albatross."

But there are instances of relative vision—especially in the great master of absolute vision, Shakespeare—which are higher still,—so high indeed that not to relegate them to absolute vision seems at first sight pedantic. Such an example is the famous speech of Lady Macbeth in the second act, where she says—

"Had he not resembled  
My father as he slept, I had done 't."

Marvellously subtle as is this speech, it will be found, if analysed, that it expresses the general human soul rather than any one special human soul. Indeed Leigh Hunt records the case of a bargeman who, charged with robbing a sleeping traveller in his barge, used in his confession almost identical words—"Had he not looked like my father as he slept, I should have killed as well as robbed him." Again, the thousand and one cases (to be found in every literature) where a character, overwhelmed by some sudden surprise or terror, asks whether the action going on is that of a dream or of real life, must all, on severe analysis, be classed under relative rather than under absolute vision,—even such a fine speech, for instance, as that where Pericles, on discovering Marina, exclaims—

"This is the rarest dream that e'er dull sleep  
Did work and fool's withal;"

or as that in the third act of *Titus Andronicus*, where Titus, beholding his mutilated and ruined daughter, asks—

"When will this fearful slumber have an end?"

even here, we say, the humanity rendered is general and not particular, the vision at work is relative and not absolute. The poet, as representing the whole human race, throwing himself into the imagined situation, gives us what general humanity would have thought, felt, said,

or done in that situation, not what one particular individual and he alone would have thought, felt, said, or done.

Now what we have called absolute vision operates in a very different way. So vividly is the poet's mere creative instinct at work that the *ego* sinks into passivity—becomes insensitive to all impressions other than those dictated by the vision—by the "divinity" which has "seized the soul."

We have left ourselves little room for examples; but Shakespeare is full of them.

Take the scene in the first act of *Hamlet* where Hamlet hears for the first time, from Horatio, that his father's ghost haunts the castle. Having by short sharp questions elicited the salient facts attending the apparition, Hamlet says, "I would I had been there." To this Horatio makes the very commonplace reply, "It would have much amazed you." Note the marvellously dramatic reply of Hamlet—"Very like, very like! Stayed it long?" Suppose that this dialogue had been attempted by any other poet than a true dramatist, or by a true dramatist in any other mood than his very highest, Hamlet, on hearing Horatio's commonplace remarks upon phenomena which to Hamlet were more subversive of the very order of the universe than if a dozen stars had fallen from their courses, would have burst out with—"Amazed me!" and then would have followed an eloquent declamation about the "amazing" nature of the phenomena and their effect upon him. But so entirely has the poet become Hamlet, so completely has "the divinity seized his soul," that all language seems equally weak for expressing the turbulence within the soul of the character, and Hamlet exclaims in a sort of meditative irony, "Very like, very like." It is exactly this one man Hamlet, and no other man, who in this situation would have so expressed himself. Charles Knight has some pertinent remarks upon this speech of Hamlet; yet he misses its true value, and treats it from the general rather than from the particular side. Instances of absolute vision in Shakespeare crowd upon us; but we can find room for only one other. In the pathetic speech of Othello, just before he kills himself, he declares himself to be—

"One not easily jealous, but, being wrought,  
Perplexed in the extreme."

Consider the marvellous *timbre* of the word "wrought," as coming from a character like Othello. When writing this passage, especially when writing this word, the poet had become entirely the simple English soldier-hero, as the Moor really is—he had become Othello, looking upon himself "as not easily jealous," whereas he was "wrought" and "perplexed in the extreme" by tricks which Hamlet would have seen through in a moment.

While all other forms of poetic art can be vitalized by where relative vision, there are two forms (and these the greatest) absolute vision is demanded, viz., the drama, and in a lesser degree the Greek epic, especially the *Iliad*. This will be seen more plainly perhaps if we now vary our definitions and call relative vision egoistic imagination, absolute vision dramatic imagination.

Drama has been already fully treated in the present work (see DRAMA). But it follows from what has been here said that very much of the dramatist's work can be, and in fact is, effected by egoistic imagination, while true dramatic imagination is only called into play on comparatively rare occasions. Not only fine but sublime dramatic poems have been written, however, where the vitalizing power has been entirely that of lyrical imagination. We need only instance the *Prometheus Bound* of Æschylus, the most sublime poem in the world. The dramas of Shelley too, like those of Victor Hugo and Calderon, are informed entirely by egoistic imagination. In all these

<sup>1</sup> Translation of Morris and Magnusson.

splendid poems the dramatist places himself in the imagined situation, or at most he places there some typical conception of universal humanity. There is not in all Calderon any such display of dramatic imagination as we get in that wonderful speech of Priam's in the last book of the *Iliad* to which we have before alluded. There is not in the *Cenci* such a display of dramatic imagination as we get in the sudden burst of anger from the spoilt child of gods and men, Achilles (anger which alarms the hero himself as much as it alarms Priam), when the prattle of the old man has carried him too far. It may seem bold to say that the drama of Goethe is informed by egoistic imagination only,—assuredly the prison-scene in *Faust* is unsurpassed in the literatures of the world. Yet, perhaps, it could be shown of the passion and the pathos of Gretchen throughout the entire play that it betrays a female character general and typical rather than individual and particular.

The nature of this absolute vision or true dramatic imagination is easily seen if we compare the dramatic work of writers without absolute vision, such as Calderon, Goethe, Ben Jonson, Fletcher, and others, with the dramatic work of Æschylus and of Shakespeare. While of the former group it may be said that each poet skilfully works his imagination, of Æschylus and Shakespeare it must be said that each in his highest dramatic mood does not work, but is worked by his imagination. Note, for instance, how the character of Clytemnestra grows and glows under the hand of Æschylus. The poet of the *Odyssey* had distinctly said that Ægisthus, her paramour, had struck the blow, but the dramatist, having imagined the greatest tragic female in all poetry, finds it impossible to let a man like Ægisthus assist such a woman in a homicide so daring and so momentous. And when in that terrible speech of hers she justifies her crime (ostensibly to the outer world, but really to her own conscience), the way in which, by the sheer magnetism of irresistible personality, she draws our sympathy to herself and her crime is unrivalled out of Shakespeare and not surpassed even there. In the Great Drama, in the *Agamemnon*, in *Othello*, in *Hamlet*, in *Macbeth*, there is an imagination at work whose laws are inexorable, are inevitable, as the laws by the operation of which the planets move around the sun. But in this essay our business with drama is confined entirely to its relations to epic.

Epic and  
drama  
com-  
pared.

Considering how large and on the whole how good is the body of modern criticism upon drama, it is surprising how poor is the modern criticism upon epic. Aristotle, comparing tragedy with epic, gives the palm to tragedy as being the more perfect art, and nothing can be more ingenious than the way in which he has marshalled his reasons. He tells us that tragedy as well as epic is capable of producing its effect even without action; we can judge of it perfectly, says he, by reading. He goes so far as to say that, even in reading as well as in representation, tragedy has an advantage over the epic, the advantage of greater clearness and distinctness of impression. And in some measure this was perhaps true of Greek tragedy, for as Müller in his *Dissertations on the Eumenides* has well said, the ancients always remained and wished to remain conscious that the whole was a Dionysian entertainment; the quest of a common-place ἀράη came afterwards. And even of Romantic Drama it may be said that in the time of Shakespeare, and indeed down through the 18th century, it never lost entirely its character of a recitation as well as a drama. It was not till melodrama began to be recognized as a legitimate form of dramatic art that the dialogue had to be struck from the dramatic action "at full speed"—struck like sparks from the roadster's shoes. The

truth is, however, that it was idle for Aristotle to inquire which is the more important branch of poetry, epic or tragedy.

Equally idle would it be for the modern critic to inquire how much romantic drama gained and how much it lost by abandoning the chorus. Much has been said as to the scope and the limits of epic and dramatic poetry. If in epic the poet has the power to take the imagination of his audience away from the dramatic centre and show what is going on at the other end of the great web of the world, he can do the same thing in drama by the chorus, and also by the introduction into the dramatic circle of messengers and others from the outside world.

But, as regards epic poetry, is it right that we should hear, as we sometimes do hear, the voice of the poet himself as chorus bidding us contrast the present picture with other pictures afar off, in order to enforce its teaching and illustrate its pathos? This is a favourite method with modern poets and a still more favourite one with prose narrators. Does it not give an air of self-consciousness to poetry? Does it not disturb the intensity of the poetic vision? Yet it has the sanction of Homer; and who shall dare to challenge the methods of the great father of epic? An instance occurs in *Iliad* v. 158, where, in the midst of all the stress of fight, the poet leaves the dramatic action to tell us what became of the inheritance of Phænops, after his two sons had been slain by Diomedes. Another instance occurs in iii. 243-4, where the poet, after Helen's pathetic mention of her brothers, comments on the causes of their absence, "criticizes life" in the approved modern way, generalizes upon the impotence of human intelligence—the impotence even of human love—to pierce the darkness in which the web of human fate is woven. Thus she spoke (the poet tells us); but the life-giving earth already possessed them, there in Lacedæmon, in their dear native land:—

ὣς φάτο· τοὺς δ' ἤδη κάτεχεν φύσις αἶα  
ἐν Λακεδαίμονι αὖθι, φίλῃ ἐν πατρίδι γαίῃ.

This of course is "beautiful exceedingly," but, inasmuch as the imagination at work is egoistic or lyrical, not dramatic, inasmuch as the vision is relative not absolute, it does not represent that epic strength at its very highest which we call specially "Homeric," unless indeed we remember that with Homer the Muses are omniscient: this certainly may give the passage a deep dramatic value it otherwise seems to lack.

The deepest of all the distinctions between dramatic and epic methods has relation, however, to the nature of the dialogue. Aristotle failed to point it out, and this is remarkable until we remember that his work is but a fragment of a great system of criticism. In epic poetry, and in all poetry that narrates, whether the poet be Homer, Chaucer, Thomas the Rhymers, Gottfried von Strasburg, or Turoldus, the action, of course, moves by aid partly of narrative and partly by aid of dialogue, but in drama the dialogue has a quality of suggestiveness and subtle inference which we do not expect to find in any other poetic form save perhaps that of the purely dramatic ballad. In ancient drama this quality of suggestiveness and subtle inference is seen not only in the dialogue, but in the choral odes. The third ode of the *Agamemnon* is an extreme case in point, where, by a kind of *double entendre*, the relations of Clytemnestra and Ægisthus are darkly alluded to under cover of allusions to Paris and Helen. Of this dramatic subtlety Sophocles is perhaps the greatest master; and certain critics have been led to speak as though irony were heart-thought of Sophoclean drama. But the suggestiveness of Sophocles is pathetic (as Prof. Lewis Campbell has well pointed out) not ironical. This is one reason why drama more than epic seems to satisfy the mere intel-

lect of the reader, though this may be counterbalanced by the hardness of mechanical structure which sometimes disturbs the reader's imagination in tragedy.

When, for instance, a dramatist pays so much attention to the evolution of the plot as Sophocles does, it is inevitable that his characters should be more or less plot-ridden; they have to say and do now and then certain things which they would not say and do but for the exigencies of the plot. Indeed one of the advantages which epic certainly has over drama is that the story can be made to move as rapidly as the poet may desire without these mechanical modifications of character.

Place of  
the *Iliad*  
in epic  
poetry.

The only kind of epic for Aristotle to consider was Greek epic, between which and all other epic the difference is one of kind, if the *Iliad* alone is taken to represent Greek epic. In speaking of the effect that surrounding conditions seem to have upon the form in which the poetic energy of any time or country should express itself, we instance the *Iliad* as a typical case. The imagination vivifying it is mainly dramatic. The characters represent much more than the mere variety of mood of the delineator. Notwithstanding all the splendid works of Calderon, Marlowe, Webster, and Goethe, it is doubtful whether as a born dramatist the poet of the *Iliad* does not come nearer to Æschylus and Shakespeare than does any other poet. His passion for making the heroes speak for themselves is almost a fault in the *Iliad* considered as pure epic, and the unconscious way in which each actor is made to depict his own character is in the highest spirit of drama. It is owing to this speciality of the *Iliad* that it stands apart from all other epic save that of the *Odyssey*, where, however, the dramatic vision is less vivid. It is owing to the dramatic imagination displayed in the *Iliad* that it is impossible to say, from internal evidence, whether the poem is to be classified with the epics of growth or with the epics of art. All epics are clearly divisible into two classes, first those which are a mere accretion of poem or traditional ballad, and second, those which, though based indeed on tradition or history, have become so fused in the mind of one great poet, so saturated, therefore, with the colour and temper of that mind, as to become new creations—invocations, in short, as we understand that word. Each kind of epic has excellencies peculiar to itself, accompanied by peculiar and indeed necessary defects. In the one we get the freedom—apparently schemeless and motiveless—of nature, but, as a consequence, miss that "hard acorn of thought" (to use the picturesque definition in the *Polaris Saga* of the heart of a man) which the mind asks for as the core of every work of art. In the other this great requisite of an adequate central thought is found, but accompanied by a constriction, a lack of freedom, a cold artificiality, the obstruction of a perceptive scheme, which would be intolerable to the natural mind unsophisticated by literary study. The flow of the one is that of a river, the flow of the other is that of a canal. Yet, as has been already hinted, though the great charm of Nature herself is that she never tires us with any obtrusive exhibitions of scheme, she doubtless has a scheme somewhere, she does somewhere hide a "hard acorn of thought" of which the poem of the universe is the expanded expression. And, this being so, art should have a scheme too; but in such a dilemma is she placed in this matter that the epic poet, unless he is evidently telling the story for its own sake, scornful of purposes ethic or æsthetic, must sacrifice illusion.

Among the former class of epics are to be placed the great epics of growth, such as the *Mahabharata*, the Nibelung story, &c.; among the latter the *Odyssey*, the *Æneid*, *Paradise Lost*, the *Jerusalem Liberata*, the *Lusiadas*.

But where in this classification are we to find a place for the *Iliad*? The heart-thought of the greatest epic in all literature is simply that Achilles was vexed and that the fortunes of the world depended upon the whim of a milky hero. Yet, notwithstanding all the recent criticisms of Wolff, it remains difficult for us to find a place for the *Iliad* among the epics of growth. And why? Because throughout the *Iliad* the dramatic imagination shown is of the first order; and, if we are to suppose a multiplicity of authors for the poem, we must also suppose that ages before the time of Pericles there existed a group of dramatists more nearly akin to the masters of the great drama, Æschylus, Sophocles, and Shakespeare than any group that has ever existed since. Yet it is equally difficult to find a place for it amongst the epics of art. In the matter of artistic motive the *Odyssey* stands alone among the epics of art of the world, as we are going to see.

It is manifest that, as the pleasure derived from the epic of art is that of recognizing a conscious scheme, if the epic of art fails through confusion of scheme it fails altogether. What is demanded of the epic of art (as some kind of compensation for that natural freedom of evolution which it can never achieve, that sweet abandon which belongs to nature and to the epic of growth alike) is unity of impression, harmonious and symmetrical development of a conscious heart-thought, or motive. This being so, where are we to place the *Æneid*, and where are we to place the *Shah Namah*? Struggling with the intention, as it seems, of fusing into one harmonious whole the myths and legends upon which the Roman story is based, Virgil, by the time he reaches the middle of his epic, forgets all about this primary intent, and gives us his own thoughts and reflections on things in general. Fine as is the speech of Anchises to Æneas in Elysium (*Æn.* vi. 724-766), its incongruity with the general scheme of the poem as developed in the previous books shows how entirely Virgil lacked that artistic power shown in the *Odyssey* of making a story become the natural and inevitable outcome of an artistic idea.

In the *Shah Namah* there is the artistic reduction of Virgil, but with even less attention to a central thought than Virgil exhibits. Firdausi relies for his effects upon the very qualities which characterize not the epic of art but the epic of growth—a natural and not an artificial flow of the story; so much so indeed that, if the *Shah Namah* were studied in connexion with the *Iliad* on the one hand and with the *Kalevala* on the other, it might throw a light upon the way in which an epic may be at one and the same time an aggregation of the national ballad poems and the work of a single artificer. That Firdausi was capable of working from a centre not only artistic but philosophic his *Yakus* and *Zakikhus* show; and if we consider what was the artistic temper of the Persians in Firdausi's time, what indeed has been that temper during the whole of the Mohammedan period, the subtle temper of the parable poet,—the *Shah Namah*, with its direct appeal to popular sympathies, is a standing wonder in poetic literature.

With regard, however, to Virgil's defective power of working from an artistic motive, as compared with the poet of the *Odyssey*, this is an infirmity he shares with all the poets of the Western world. Certainly he shares it with the writer of *Paradise Lost*, who, setting out to "justify the ways of God to man," forgets occasionally the original worker of the evil, as when, for instance, he substitutes chance as soon as he comes (at the end of the second book) to the point upon which the entire epic movement turns, the escape of Satan from hell and his journey to earth for the ruin of man:—

"At last his sail-broad vans  
He spreads for flight, and, in the surging smoke  
Uplifted, spurns the ground; thence many a league,  
As in a cloudy chair, ascending rides  
Audacious; but, that seat soon failing, meets  
A vast vacuity; all unawares,  
Fluttering his pinions vain, plumb down he drops  
Ten thousand fathoms deep, and to this hour  
Down had been falling, had not, by ILL CHANCE,  
The strong rebuff of some tumultuous cloud,  
Instinct with fire and nitre, hurried him  
As many miles aloft."

In Milton's case, however, the truth is that he made the mistake of trying to disturb the motive of a story for artistic purposes,—a fatal mistake as we shall see when we come to speak of the *Nibelungenlied* in relation to the old Norse epic cycle.

Though Vondel's mystery play of *Lucifer* is, in its execution, rhetorical more than poetical, it did, beyond all question, influence Milton when he came to write *Paradise Lost*. The famous line which is generally quoted as the key-note of Satan's character—

"Better to reign in hell than serve in heaven"—

seems to have been taken bodily from Vondel's play, and Milton's entire epic shows a study of it. While Marlowe's majestic movements alone are traceable in Satan's speech (written some years before the rest of *Paradise Lost*, when the dramatic and not the epic form had been selected), Milton's Satan became afterwards a splendid amalgam not of the Mephistopheles but of the *Faustus* of Marlowe and the *Lucifer* of Vondel. Vondel's play must have possessed a peculiar attraction for a poet of Milton's views of human progress. Defective as the play is in execution, it is far otherwise in motive. This motive, if we consider it aright, is nothing less than an explanation of man's anomalous condition on the earth—spirit incarnate in matter, created by God, a little lower than the angels—in order that he may advance by means of these very manacles which imprison him, in order that he may ascend by the staircase of the world, the ladder of fleshly conditions, above those cherubim and seraphim who, lacking the education of sense, have not the knowledge wide and deep which brings man close to God.

Here Milton found his own favourite doctrine of human development and self-education in a concrete and vividly artistic form. Much, however, as such a motive must have struck a man of Milton's instincts, his intellect was too much chained by Calvinism to permit of his treating the subject with Vondel's philosophic breadth. The cause of Lucifer's wrath had to be changed from jealousy of human progress to jealousy of the Son's proclaimed superiority. And the history of poetry shows that once any group of incidents has crystallized and the entire story becomes thereby re-written, as we have seen in the case of the *Agamemnon* of Æschylus. Of the motive of his own epic, after he had abandoned the motive of Vondel, Milton had as little permanent grasp as Virgil had of his. As regards the *Odyssey*, however, we need scarcely say that its motive is merely artistic, not philosophic. And now we come to philosophic motive.

Philosophic motive.

The artist's power of thought is properly shown not in the direct enunciation of ideas but in mastery over motive. Here Æschylus is by far the greatest figure in Western poetry,—a proof perhaps among many proofs of the Oriental strain of his genius. (As regards pure drama, however, important as is motive, freedom, organic vitality in every part, is of more importance than even motive, and in this freedom and easy abandonment the concluding part of the *Oresteia* is deficient as compared with such a play as *Othello* or *Lear*.) Notwithstanding the splendid exception of Æschylus, the truth seems to be that the

faculty of developing a poetical narrative from a philosophic thought is Oriental, and on the whole foreign to the genius of the Western mind. Neither in Western drama nor in western epic do we find, save in such rare cases as that of Vondel, anything like that power of developing a story from an idea which not only Jami but all the parable poets of Persia show.

In recent English poetry, the motive of Shelley's dramatic poem *Prometheus Unbound* is a notable illustration of what is here contended. Starting with the full intent of developing a drama from a motive—starting with a universalism, a belief that good shall be the final goal of ill—Shelley cannot finish his first three hundred lines without shifting (in the curse of Prometheus) into a Manichæism as pure as that of Manes himself:—

"Heap on thy soul, by virtue of this curse,  
Ill deeds, then be thou damned, beholding good;  
Both infinite as is the universe."

According to the central thought of the poem human nature, through the heroic protest and struggle of the human mind typified by Prometheus, can at last dethrone that supernatural terror and tyranny (Jupiter) which the human mind had itself installed. But, after its dethronement (when human nature becomes infinitely perfectible), how can the supernatural tyranny exist apart from the human mind that imagined it? How can it be as "infinite as the universe"?

The motive of *Paradise Lost* is assailed with much vigour by Victor Hugo in his poem *Religions et Religion*. But when M. Hugo, in the after parts of the poem, having destroyed Milton's "God," sets up an entirely French "Dieu" of his own and tries "to justify" him, we perceive how pardonable was Milton's failure after all. Compare such defect of mental grip and such nebulousity of thought as is displayed by Milton, Shelley, and M. Hugo with the strength of hand shown in the "Salamán" and "Absal" of Jami, and indeed by the Sufi poets generally.

There is, however, one exception to this rule that The Great Western poetry is nebulous as to motive. There is, besides Northern the *Iliad*, one epic that refuses to be classified, though epic for entirely different reasons. This is the Niblung story, where we find unity of purpose and also entire freedom of movement. We find combined here beauties which are nowhere else combined—which are, in fact, at war with each other everywhere else. We find a scheme, a real "acorn of thought," in an epic which is not the self-conscious work of a single poetic artificer, but is as much the slow growth of various times and various minds as is the *Mahābhārata*, in which the heart-thought is merely that the Kauravas defeated their relatives at dice and refused to disgorge their winnings.

This Northern epic-tree, as we find it in the Icelandic sagas, the Norns themselves must have watered; for it combines the virtues of the epic of growth with those of the epic of art. Though not written in metre, it may usefully be compared with the epics of Greece and of India and Persia. Free in movement as the wind, which "bloweth where it listeth," it listeth to move by law. Its action is that of free-will, but free-will at play within a ring of necessity. Within this ring there throbs all the warm and passionate life of the world outside, and all the freedom apparently. Yet from that world it is enisled by a cordon of curses—by a zone of defiant flames more impregnable than that which girdled the beautiful Brynhild at Hindfell. Natural laws, familiar emotions, are at work everywhere in the story; yet the "Ring of Andvari," whose circumference is but that of a woman's finger, encircles the whole mimic world of the sagaman as the Midgard snake encircles the earth. For this artistic perfection in an epic of growth there are,

kind from all other lyrics as to stand in a class by itself. As it is equal in importance to the Great Drama of Shakespeare, Æschylus, and Sophocles, we may perhaps be allowed to call it the "Great Lyric." The Great Lyric must be religious—it must, it would seem, be an outpouring of the soul, not towards man but towards God, like that of the God-intoxicated prophets and psalmists of Scriptura. Even the lyric fire of Pindar owes much to the fact that he had a child-like belief in the myths to which so many of his contemporaries had begun to give a languid assent. But there is nothing in Pindar, or indeed elsewhere in Greek poetry, like the rapturous song, combining unconscious power with unconscious grace, which we have called the Great Lyric. It might perhaps be said indeed that the Great Lyric is purely Hebrew.

The great lyric of the Hebrews stands alone.

But, although we could hardly expect to find it among those whose language, complex of syntax and alive with self-conscious inflexions, bespeaks the scientific knowingness of the Western mind, to call the temper of the Great Lyric broadly "Asiatic" would be rash. It seems to belong as a birthright to those descendants of Shem who, yearning always to look straight into the face of God and live, could (when the Great Lyric was sung) see not much else.

Though two of the artistic elements of the Great Lyric, unconsciousness and power, are no doubt plentiful enough in India, the element of grace is lacking for the most part. The Vedic hymns are both nebulous and unemotional, as compared with Semitic hymns. And as to the Persians, they, it would seem, have the grace always, the power often, but the unconsciousness almost never. This is inevitable if we consider for a moment the chief characteristic of the Persian imagination—an imagination whose wings are not so much "bright with beauty" as heavy with it—heavy as the wings of a golden pheasant—steeped in beauty like the "tiger-moth's deep damasked wings." Now beauty of this kind does not go to the making of the Great Lyric.

Then there comes that poetry which, being ethnologically Semitic, might be supposed to exhibit something at least of the Hebrew temper—the Arabian. But, whatever may be said of the oldest Arabic poetry, with its deep sense of fate and pain, it would seem that nothing can be more unlike than the Hebrew temper and the Arabian temper as seen in later poets. It is not with Hebrew but with Persian poetry that Arabian poetry can be usefully compared. If the wings of the Persian imagination are heavy with beauty, those of the later Arabian imagination are bright with beauty—brilliant as an Eastern butterfly, quick and agile as a dragon-fly or a humming-bird. To the eye of the Persian poet the hues of earth are (as Firdausi says of the garden of Afrasiab) "like the tapestry of the kings of Ormuz, the air is perfumed with musk, and the waters of the brooks are the essence of roses." And to the later Arabian no less than to the Persian the earth is beautiful; but it is the clear and sparkling beauty of the earth as she "wakes up to life, greeting the Sabæan morning": we feel the light more than the colour.

But it is neither the Persian's instinct for beauty nor the Arabian's quenchless wit and exhaustless animal spirits that go to the making of the Great Lyric; far from it. In a word, the Great Lyric, as we have said, cannot be assigned to the Asiatic temper generally any more than it can be assigned to the European temper.

In the poetry of Europe, if we cannot say of Pindar, devout as he is, that he produced the Great Lyric, what can we say of any other European poet? The truth is that, like the Great Drama, so straight and so warm does it seem to come from the heart of man in its highest moods that we scarcely feel it to be literature at all.

Passing, however, from this supreme expression of lyrical imagination, we come to the artistic ode, upon which <sup>The artistic ode of Greece.</sup> subject the present writer can only reiterate here what he has more fully said upon a former occasion. What ever may have been said to the contrary, enthusiasm is, in the nature of things, the very basis of the ode; for the ode is a mono-drama, the actor in which is the poet himself; and, as Marmontel has well pointed out, if the actor in the mono-drama is not affected by the sentiments he expresses, the ode must be cold and lifeless. But, although the ode is a natural poetic method of the poet considered as prophet—although it is the voice of poetry as a fine frenzy—it must not be supposed that there is anything lawless in its structure. "Pindar," says the Italian critic Gravina, "launches his verses upon the bosom of the sea; he spreads out all his sails; he confronts the tempest and the rocks; the waves arise and are ready to engulf him; already he has disappeared from the spectator's view; when suddenly he springs up in the midst of the waters, and reaches happily the shore." Now it is this Pindaric discursiveness, this Pindaric unrestraint as to the matter, which has led poets to attempt to imitate him by adopting an unrestraint as to form. Although no two odes of Pindar exhibit the same metrical structure (the Æolian and Lydian rhythms being mingled with the Doric in different proportions), yet each ode is in itself obedient, severely obedient, to structural law. This we feel; but what the law is no metricist has perhaps ever yet been able to explain.

It was a strange misconception that led people for centuries to use the word "Pindaric" and irregular as synonymous terms; whereas the very essence of the odes of Pindar (of the few, alas! which survive to us) is their regularity. There is no more difficult form of poetry than this, and for this reason: when in any poetical composition the metres are varied, there must, as the present writer has before pointed out, be a reason for such freedom, and that reason is properly subjective—the varying form must embody and express the varying emotions of the singer. But when these metrical variations are governed by no subjective law at all, but by arbitrary rules supposed to be evolved from the practice of Pindar, then that very variety which should aid the poet in expressing his emotion crystallizes it and makes the ode the most frigid of all compositions. Great as Pindar undoubtedly is, it is deeply to be regretted that no other poet survives to represent the triumphal ode of Greece,—the digressions of his subject-matter are so wide, and his volubility is so great.

In modern literature the ode has been ruined by theories <sup>The modern ode.</sup> and experiments. A poet like La Motte, for instance, writes execrable odes, and then writes a treatise to prove that all odes should be written on the same model.

There is much confusion of mind prevalent among poets as to what is and what is not an ode. All odes are, no doubt, divisible into two great classes:—those which following an arrangement in stanzas, are commonly called regular, and those which, following no such arrangement, are commonly called irregular.

We do not agree with those who assert that irregular <sup>The irregular or pseudo-Pindaric ode.</sup> metres are of necessity inimical to poetic art. On the contrary, we believe that in modern prosody the arrangement of the rhymes and the length of the lines in any rhymed metrical passage may be determined either by a fixed stanzaic law or by a law infinitely deeper—by the law which impels the soul, in a state of poetic exaltation, to seize hold of every kind of metrical aid, such as rhyme, cæsura, &c., for the purpose of accentuating and marking off each shade of emotion as it arises, regardless of any demands of stanza. But between the irregularity of makeshift, such as we find it in Cowley and his imitators, and

the irregularity of the "fine frenzy" of such a poem, for instance, as Coleridge's *Kubla Khan*, there is a difference in kind. Strange that it is not in an ode at all but in this unique lyric *Kubla Khan*, descriptive of imaginative landscape, that an English poet has at last conquered the crowning difficulty of writing in irregular metres. Having broken away from all restraints of couplet and stanza,—having caused his rhymes and pauses to fall just where and just when the emotion demands that they should fall, scorning the exigencies of makeshift no less than the exigencies of stanza,—he has found what every writer of irregular English odes has sought in vain, a music as entrancing, as natural, and at the same time as inscrutable, as the music of the winds or of the sea.

Stanzaic  
law and  
emo-  
tional  
law.

The prearranged effects of sharp contrasts and antiphonal movements, such as some poets have been able to compass, do not of course come under the present definition of irregular metres at all. If a metrical passage does not gain immensely by being written independently of stanzaic law, it loses immensely; and for this reason, perhaps, that the great charm of the music of all verse, as distinguished from the music of prose, is inevitableness of cadence. In regular metres we enjoy the pleasure of feeling that the rhymes will inevitably fall under a recognized law of couplet or stanza. But if the passage flows independently of these, it must still flow inevitably—it must, in short, show that it is governed by another and a yet deeper force, the inevitableness of emotional expression. The lines must be long or short, the rhymes must be arranged after this or after that interval, not because it is convenient so to arrange them, but because the emotion of the poet inexorably demands these and no other arrangements. When, however, Coleridge came to try his hand at irregular odes, such as the odes "To the Departing Year" and "To the Duchess of Devonshire," he certainly did not succeed.

As to Wordsworth's magnificent "Ode on Intimations of Immortality," the sole impeachment of it, but it is a grave one, is that the length of the lines and the arrangement of the rhymes are not always inevitable; they are, except on rare occasions, governed neither by stanzaic nor by emotional law. For instance, what emotional necessity was there for the following rhyme-arrangement?

"My heart is at your festival,  
My head hath its coronal,  
The fulfils of your bliss I feel—I feel it all.  
Oh, evil day! if I were sullen  
While earth herself is adorning,  
This sweet May morning;  
And the children are culling,  
On every side,  
In a thousand valleys far and wide,  
Fresh flowers."

Beautiful as is the substance of this entire passage, so far from gaining, it loses by rhyme—loses, not in perspicuity, for Wordsworth like all his contemporaries (except Shelley) is mostly perspicuous, but in that metrical emphasis the quest of which is one of the impulses that leads a poet to write in rhyme. In spite, however, of its metrical defects, this famous ode of Wordsworth's is the finest irregular ode in the language; for, although Coleridge's "Ode to the Departing Year" excels it in Pindaric fire, it is below Wordsworth's masterpiece in almost every other quality save rhythm. Among the writers of English irregular odes, next to Wordsworth, stands Dryden. The second stanza of the "Ode for St Cecilia's Day" is a great triumph.

The true Pindaric ode is regular. Leaving the irregular and turning to the regular ode, it is natural to divide these into two classes:—(1) those which are really Pindaric in so far as they consist of strophes, antistrophes, and epodes, variously arranged and

contrasted; and (2) those which consist of a regular succession of regular stanzas. Perhaps all Pindaric odes tend to show that this form of art is in English a mistake. It is easy enough to write one stanza and call it a strophe, another in a different movement and call it an antistrophe, a third in a different movement still and call it an epode. But in modern prosody, disconnected as it is from musical and from terpsichorean science, what are these? No poet and no critic can say.

What is requisite is that the ear of the reader should catch a great metrical scheme, of which these three varieties of movement are necessary parts,—should catch, in short, that inevitableness of structure upon which we have already touched. In order to justify a poet in writing a poem in three different kinds of movement, governed by no musical and no terpsichorean necessity, a necessity of another kind should make itself apparent; that is, the metrical wave moving in the strophe should be metricaly answered by the counter-wave moving in the antistrophe, while the epode—which, as originally conceived by Stesichorus, was merely a standing still after the balanced movements of the strophe and antistrophe—should clearly, in a language like ours, be a blended echo of these two. A mere metrical contrast such as some poets labour to effect is not a metrical answer. And if the reply to this criticism be that in Pindar himself no such metrical scheme is apparent, that is the strongest possible argument in support of our position. If indeed the metrical scheme of Pindar is not apparent, that is because, having been written for chanting, it was subordinate to the lost musical scheme of the musician. It has been contended, and is likely enough, that this musical scheme was simple—as simple, perhaps, as the scheme of a cathedral chant; but to it, whatever it was, the metrical scheme of the poet was subordinated. It need scarcely be said that the phrase "metrical scheme" is used here not in the narrow sense as indicating the position and movement of strophe and antistrophe by way of simple contrast, but in the deep metrical sense as indicating the value of each of these component parts of the ode, as a counter-wave balancing and explaining the other waves in the harmony of the entire composition. We touch upon this matter in order to show that the moment odes ceased to be chanted, the words strophe, antistrophe, and epode lost the musical value they had among the Greeks, and pretended to a complex metrical value which their actual metrical structure does not appear to justify. It does not follow from this that odes should not be so arranged, but it does follow that the poet's arrangement should justify itself by disclosing an entire metrical scheme in place of the musical scheme to which the Greek choral lyric was evidently subordinated. But even if the poet were a sufficiently skilled metrist to compass a scheme embracing a wave, an answering wave, and an echo gathering up the tones of each, i.e., the strophe, the antistrophe, and the epode, the ear of the reader, unaided by the musical emphasis which supported the rhythms of the old choral lyric, is, it should seem, incapable of gathering up and remembering the sounds further than the strophe and the antistrophe, after which it demands not an epode but a return to the strophe. That is to say, an epode, as alternating in the body of the modern ode, is a mistake; a single epode at the end of a group of strophes and antistrophes (as in some of the Greek odes) has, of course, a different function altogether.

The great difficulty of the English ode is that of preventing the apparent spontaneity of the impulse from being marred by the apparent artifice of the form; for, assuredly, no writer subsequent to Coleridge and to Keats would dream of writing an ode on the cold Horatian principles

adopted by Warton, and even by Collins, in his beautiful "Ode to Evening."

The  
simple  
odes of  
regular  
stanzas.

Of the second kind of regular odes, those consisting of a regular succession of regular stanzas, the so-called odes of Sappho are, of course, so transcendent that no other amatory lyrics can be compared with them. Never before these songs were sung and never since did the human soul, in the grip of a fiery passion, utter a cry like hers; and, from the executive point of view, in directness, in lucidity, in that high imperious verbal economy which only Nature herself can teach the artist, she has no equal, and none worthy to take the place of second—not even in Heine, not even in Burns. Turning, however, to modern poetry, there are some magnificent examples of this simple form of ode in English poetry—Spenser's immortal "Epithalamion" leading the way in point of time, and probably also in point of excellence.

Fervour being absolutely essential, we think, to a great English ode, fluidity of metrical movement can never be dispensed with. The more billowy the metrical waves the better suited are they to render the emotions expressed by the ode, as the reader will see by referring to Coleridge's "Ode to France" (the finest ode in the English language, according to Shelley), and giving special attention to the first stanza—to the way in which the first metrical wave, after it had gently fallen at the end of the first quatrain, leaps up again on the double rhymes (which are expressly introduced for this effect), and goes bounding on, billow after billow, to the end of the stanza. Not that this fine ode is quite free from the great vice of the English ode, rhetoric. If we except Spenser and, in one instance, Collins, it can hardly be said that any English writer before Shelley and Keats produced odes independent of rhetoric and supported by pure poetry alone. But fervid as are Shelley's "Ode to the West Wind," and Keats's Odes "To a Nightingale" and "On a Grecian Urn," they are entirely free from rhetorical flavour. Notwithstanding that in the "Ode on a Grecian Urn" the first stanza does not match in rhyme arrangement with the others, while the second stanza of the "Ode to a Nightingale" varies from the rest by running on four rhyme-sounds instead of five, vexing the ear at first by disappointed expectation, these two odes are, after Coleridge's "France," the finest regular odes perhaps in the English language.

The  
French  
ode.

With regard to the French ode, Malherbe was the first writer who brought it to perfection. Malherbe showed also more variety of mood than it is the fashion just now to credit him with. This may be especially noted in his "Ode to Louis XIII." His disciple Racan is not of much account. There is certainly much vigour in the odes of Rousseau, but it is not till we reach Victor Hugo that we realize what French poetry can achieve in this line; and contemporary poetry can hardly be examined here. We may say, however, that some of Hugo's odes are truly magnificent. As a pure lyrist his place among the greatest poets of the world is very high. Here, though writing in an inferior language, he ranks with the greatest masters of Greece, of England, and of Germany. Had he attempted no other kind of poetry than lyrical, his would still have been the first name in French poetry. Whatever is defective in his work arises, as in the case of Euripides, from the importation of lyrical force where dramatic force is mainly needed.

As most of the other varieties of lyrical poetry, such as the idyl, the satire, the ballad, the sonnet, &c., have been or will be treated under different heads, or under the names of the various masters of poetic art, it would be superfluous to discuss them here.

A word or two, however, must be said about the song and the elegy. To write a good song requires that simpli-

city of grammatical structure which is foreign to many natures—that mastery over direct and simple speech which only true passion and feeling can give, and which "coming from the heart goes to the heart." Without going so far as to say that no man is a poet who cannot write a good song, it may certainly be said that no man can write a good song who is not a good poet.

In modern times we have, of course, nothing in any way representing those choral dance-songs of the Greeks, which, originating in the primitive Cretan war-dances, became, in Pindar's time, a splendid blending of song and ballet. Nor have we anything exactly representing the Greek *scolia*, those short drinking songs of which Terpander is said to have been the inventor. That these *scolia* were written, not only by poets like Alcæus, Anacreon, Praxilla, Simonides, but also by Sappho and by Pindar shows in what high esteem they were held by the Greeks. These songs seem to have been as brief as the *stornelli* of the Italian peasant. They were accompanied by the lyre, which was handed from singer to singer as the time for each *scolion* came round.

The  
Italian  
improvisatorial  
peasant  
poetry.

With regard to the *stornello*, many critics seem to confound it with the *rispetto*, a very different kind of song. The Italian *rispetto* consists of a stanza of inter-rhyming lines ranging from six to ten in number, but often not exceeding eight. The Tuscan and Umbrian *stornello* is much shorter, consisting, indeed, of a hemistich naming some natural object which suggests the motive of the little poem.

The nearest approach to the Italian *stornello* appears to be, not the *rispetto*, but the Welsh *triban*.

Perhaps the mere difficulty of rhyming in English and the facility of rhyming in Italian must be taken into account when we inquire why there is nothing in Scotland—of course there could be nothing in England—answering to the nature-poetry of the Italian peasant. Most of the Italian *rispetti* and *stornelli* seem to be improvisations; and to improvise in English is as difficult as to improvise is easy in Italian. Nothing indeed is more interesting than the improvisatorial poetry of the Italian peasants, such as the *canzone*. If the peasantry discover who is the composer of a *canzone*, they will not sing it. The speciality of Italian peasant poetry is that the symbol which is mostly erotic is of the purest and most tender kind. A peasant girl will improvise a song as impassioned as "Come into the Garden, Maud," and as free from unwholesome taint.

With regard to English songs, the critic cannot but ask—Wherein lies the lost ring and charm of the Elizabethan song-writers? Since the Jacobean period at least, few have succeeded in the art of writing real songs as distinguished from mere book lyrics. Between songs to be sung and songs to be read there is in our time a difference as wide as that which exists between plays for the closet and plays for the boards.

Heartiness and melody—the two requisites of a song which can never be dispensed with—can rarely be compassed, it seems, by one and the same individual. In both these qualities the Elizabethan poets stand pre-eminent, though even with them the melody is not so singable as it might be made. Since their time heartiness has, perhaps, been a Scottish rather than an English endowment of the song-writer. It is difficult to imagine an Englishman writing a song like "Tullochgorum" or a song like "Maggie Lauder," where the heartiness and impulse of the poet's mood conquer all impediments of close vowels and rugged consonantal combinations. Of Scottish song-writers Burns is, of course, the head; for the songs of John Skinner, the heartiest song-writer that has appeared in Great Britain (not excluding Herrick), are too few in

number to entitle him to be placed beside a poet so prolific in heartiness and melody as Burns. With regard to Campbell's heartiness, this is quite a different quality from the heartiness of Burns and Skinner, and is in quality English rather than Scottish, though, no doubt, it is of a fine and rare strain, especially in "The Battle of the Baltic." His songs illustrate an infirmity which even the Scottish song-writers share with the English—a defective sense of that true song-warble which we get in the stornelli and rispetti of the Italian peasants. A poet may have heartiness in plenty, but if he has that love of consonantal effects which Donne displays he will never write a first-rate song. Here, indeed, is the crowning difficulty of song-writing. An extreme simplicity of structure and of diction must be accompanied by an instinctive apprehension of the melodic capabilities of verbal sounds, and of what Samuel Lover, the Irish song-writer, called "singing" words, which is rare in this country, and seems to belong to the Celtic rather than to the Saxon ear. "The song-writer," says Lover, "must frame his song of open vowels with as few guttural or hissing sounds as possible, and he must be content sometimes to sacrifice grandeur and vigour to the necessity of selecting singing words and not reading words." And he exemplifies the distinction between singing words and reading words by a line from one of Shelley's songs—

"The fresh earth in new leaves drest,"

"where nearly every word shuts up the mouth instead of opening it." But closeness of vowel sounds is by no means the only thing to be avoided in song-writing. A phrase may be absolutely unsingable, though the vowels be open enough, if it is loaded with consonants. The truth is that in song-writing it is quite as important, in a consonantal language like ours, to attend to the consonants as to the vowels; and perhaps the first thing to avoid in writing English songs is the frequent recurrence of the sibilant. But this applies to all the brief and quintessential forms of poetry, such as the sonnet, the elegy, &c.

The elegy. As to the elegy—a form of poetic art which has more relation to the objects of the external world than the song, but less relation to these than the stornello—its scope seems to be wide indeed, as practised by such various

writers as Tyrtæus, Theognis, Catullus, Tibullus, and our own Gray. It may almost be said that perfection of form is more necessary here and in the sonnet than in the song, inasmuch as the artistic pretensions are more pronounced. Hence even such apparent minutiae as those we have hinted at above must not be neglected here.

We have quoted Dionysius of Halicarnassus in relation to the arrangement of words in poetry. His remarks on sibilants are equally deserving of attention. He goes so far as to say that  $\sigma$  is entirely disagreeable, and, when it often recurs, insupportable. The hiss seems to him to be more appropriate to the beast than to man. Hence certain writers, he says, often avoid it, and employ it with regret. Some, he tells us, have composed entire odes without it. But if sibilation is a defect in Greek odes, where the softening effect of the vowel sounds is so potent, it is much more so in English poetry, where the consonants dominate, though it will be only specially noticeable in the brief and quintessential forms such as the song, the sonnet, the elegy. Many poets only attend to their sibilants when these clog the rhythm. To write even the briefest song without a sibilant would be a *tour de force*; to write a good one would no doubt be next to impossible. It is singular that the only metrist who ever attempted it was John Thelwall, the famous "Citizen John," friend of Lamb and Coleridge, and editor of the famous *Champion* newspaper where many of Lamb's epigrams appeared. Thelwall gave much attention to metrical questions, and tried his hand at various metres. Though "Citizen John's" sapphics might certainly have been better, he had a very remarkable critical insight into the rationale of metrical effects, and his "Song without a Sibilant" is extremely neat and ingenious. Of course, however, it would be mere pedantry to exaggerate this objection to sibilants even in these brief forms of poetry.

As a fine art English poetry is receiving much attention in our time. Defective rhymes once allowable, and makeshift work in general, are no longer tolerated. And we believe the time is not far distant when even such a subject as vowel composition (the arrangement of one vowel sound with regard to another) will have to be studied with the care which the Greeks evidently bestowed upon it. (T. W.)

POGGENDORFF, JOHANN CHRISTIAN (1796–1877), physicist, and editor for more than half a century of the well-known scientific journal called after him *Poggendorff's Annalen*, was born in Hamburg on the 29th December 1796. His father, a wealthy manufacturer of that town, was all but ruined by the French siege. His son Christian, after receiving his education at Hamburg and Schiffbeck, had therefore, when only sixteen, to apprentice himself to an apothecary in Hamburg, and when twenty-two began to earn his living as an apothecary's assistant at Itzehoe. Ambition and a strong inclination towards a scientific career led him to throw up his business and remove to Berlin, where he entered the university in 1820. Here his abilities were speedily recognized, and in 1823 he was appointed meteorological observer to the Academy of Sciences with a small salary, which was important to him, inasmuch as the expenses of his university career had nearly exhausted his slender patrimony. Even at this early period he had conceived the idea of founding a physical and chemical scientific journal. The realization of this plan was hastened by the sudden death of Gilbert, the editor of *Gilbert's Annalen der Physik*, in 1824. Poggendorff immediately put himself in communication with the publisher, Barth of Leipsic, with the result that

he was installed as editor of a scientific journal which was to be a continuation of *Gilbert's Annalen* on a somewhat extended plan, indicated by its title *Annalen der Physik und Chemie*. Poggendorff was admirably qualified for the post which he thus attained. He had an extraordinary memory, well-stored with scientific knowledge, both modern and historical, which served him in good stead in the critical part of his editorial duty. He had a cool and impartial judgment, with a strong preference for facts as against theory of the speculative kind at least, and was able to throw himself into the spirit of modern experimental science, represented in the early part of his editorial career by such great names as Berzelius, Faraday, Brewster, Fresnel, Regnault. He also possessed in more than German measure the German virtue of orderliness in the arrangement of knowledge and in the conduct of business. To this he added an engaging geniality of manner and much tact in dealing with men; so marked in fact was this part of his character that, notwithstanding his somewhat trying position, he never during his long life was involved in anything that could be fairly called a literary quarrel. These qualities of its editor soon made *Poggendorff's Annalen* the foremost scientific journal in Europe. He collected around him all the eminent scien-

tific men of his own country, and he managed, either through original contributions or by translations of memoirs of approved value already printed, to secure for many years an adequate representation of the scientific work of other lands. So true is this that, for years after the beginning of Poggendorff's editorship, the tables of contents of his annual volumes read like an index of the history of physical science.

In the course of his fifty-two years' editorship of the *Annalen* Poggendorff could not fail to acquire an unusual acquaintance with the labours of modern men of science. This knowledge, joined to what he had gathered by historical reading of equally unusual extent, he carefully digested and gave to the world in his *Biographisch-literarisches Handbuch zur Geschichte der Exakten Wissenschaften*, containing notices of the lives and labours of mathematicians, astronomers, physicists, chemists, mineralogists, geologists, &c., of all peoples and all ages. The two volumes of this work contain an astounding collection of facts invaluable to the scientific biographer and historian; they form in fact the basis of the yet unwritten history of physical science. We possess a small fragment of such a history in the form of lectures delivered by Poggendorff himself at Berlin; and probably he had contemplated at one time writing a continuous narrative; but even his long life was too short for the double task of collecting and using the material.

Poggendorff was a physicist of high although not of the very highest rank. He was wanting in mathematical ability, and never displayed in any remarkable degree the still more important power of scientific generalization, which, whether accompanied by mathematical skill or not, never fails to mark the highest genius in physical science. He was, however, an able and conscientious experimenter. He was very fertile and ingenious in devising physical apparatus, and contributed greatly in the earlier part of his life to enrich the resources of experimental science. Contemporaneously with Schweigger, he succeeded in greatly increasing the sensitiveness of the galvanometer by introducing the multiplying coil, and he made important improvements on that particular type of this instrument which is usually called the sine galvanometer. To him (according to Wiedemann) we owe the use of binding screws in most of their various forms. He invented the "Inversor" for rapidly alternating the direction of a voltaic current, and the "Wippe" for throwing a number of voltaic or electrolytic cells suddenly into "series" or into "multiple arc"; and to him is due the suggestion of the telescope and mirror method for reading galvanometers and other physical instruments, a device which has proved very valuable in all branches of physical science.

Poggendorff's contributions to physics were published for the most part in his own journal. They form an important part of the scientific work of the 19th century; but it would be difficult in a few words to characterize them inasmuch as they do not constitute a single coherent group or even a few coherent groups of connected researches. By far the greater and more important part of his work related to electricity and magnetism. As specimens we may mention his investigations into the working of Holtz's machines, and his variations on their construction; his researches on the resistance and electromotive force of electrolytic cells, along with which ought to be noticed his admirable method of comparing electromotive forces by "compensation"; and finally his researches on magnetism and diamagnetism.

Poggendorff's literary and scientific reputation speedily brought him honourable recognition. In 1830 he was made royal professor and in 1834 Hon. Ph.D. and extraordinary professor in the university of Berlin, and in

1839 member of the Berlin Academy of Sciences. He ultimately became a member of many foreign societies, and received more than the usual share of the orders bestowed by Continental nations for scientific merit. During his lifetime many offers of ordinary professorships were made to him, but he declined them all, devoting himself to his duties as editor of the *Annalen*, and to the pursuit of his scientific researches. He died at Berlin on January 24, 1877.

POGGIO (1380-1459). Gian Francesco Poggio Bracciolini, eminent in the annals of the revival of learning, was born in 1380 at Terranova, a village in the territory of Florence. He studied Latin under John of Ravenna, and Greek under Manuel Chrysoloras. His distinguished abilities and his dexterity as a copyist of MSS. brought him into early notice with the chief scholars of Florence. Coluccio Salutati and Niccolo de' Niccoli befriended him, and in the year 1402 or 1403 he was received into the service of the Roman curia. His functions were those of a secretary; and, though he profited by benefices conferred on him in lieu of salary, he remained a layman to the end of his life. It is noticeable that, while he held his office in the curia through that momentous period of fifty years which witnessed the councils of Constance and of Basel, and the final restoration of the papacy under Nicholas V., his sympathies were never attracted to ecclesiastical affairs. Nothing marks the secular attitude of the Italians at an epoch which decided the future course of both Renaissance and Reformation more strongly than the mundane proclivities of this apostolic secretary, heart and soul devoted to the resuscitation of classical studies amid conflicts of popes and antipopes, cardinals and councils, in all of which he bore an official part. Thus, when his duties called him to Constance in 1414, he employed his leisure in exploring the libraries of Swiss and Swabian convents. The treasures he brought to light at Reichenau, Weingarten, and above all at St Gall, restored many lost masterpieces of Latin literature, and supplied students with the texts of authors whose works had hitherto been accessible only in mutilated copies. In one of his epistles he describes how he recovered Quintilian, part of Valerius Flaccus, and the commentaries of Asconius Pedianus at St Gall. MSS. of Lucretius, Columella, Silius Italicus, Manilius, and Vitruvius were unearthed, copied by his hand, and communicated to the learned. Wherever Poggio went he carried on the same industry of research. At Langres he discovered Cicero's *Oration for Cæcina*, at Monte Cassino a MS. of Frontinus. He also could boast of having recovered Ammianus Marcellinus, Nonius Marcellus, Probus, Flavius Caprarius, and Eutyches. If a codex could not be obtained by fair means, he was ready to use fraud, as when he bribed a monk to abstract a Livy and an Ammianus from the convent library of Hersfeld. Resolute in recognizing erudition as the chief concern of man, he sighed over the folly of popes and princes, who spent their time in wars and ecclesiastical disputes when they might have been more profitably employed in reviving the lost learning of antiquity. This point of view is eminently characteristic of the earlier Italian Renaissance. The men of that nation and of that epoch were bent on creating a new intellectual atmosphere for Europe by means of vital contact with antiquity. Poggio, like a still more eminent humanist of his age, Æneas Sylvius Piccolomini, was a great traveller, and wherever he went he brought, like Æneas Sylvius, enlightened powers of observation trained in liberal studies to bear upon the manners of the countries he visited. We owe to his pen curious remarks on English and Swiss customs, valuable notes on the remains of antique art in Rome, and a singularly striking portrait of Jerome of Prague as he

appeared before the judges who condemned him to the stake. It is necessary to dwell at length upon Poggio's devotion to the task of recovering the classics, and upon his disengagement from all but humanistic interests, because these were the most marked feature of his character and career. In literature he embraced the whole sphere of contemporary studies, and distinguished himself as an orator, a writer of rhetorical treatises, a panegyrist of the dead, a violent impugner of the living, a translator from the Greek, an epistolographer and grave historian, and a facetious compiler of fabliaux in Latin. Of his moral essays it may suffice to notice the dissertations *On Nobility*, *On Vicissitudes of Fortune*, *On the Misery of Human Life*, *On the Infelicity of Princes*, and *On Marriage in Old Age*. These compositions belonged to a species which, since Petrarch set the fashion, were very popular among Italian scholars. They have lost their value, except for the few matters of fact embedded in a mass of commonplace meditation, and for some occasionally brilliant illustrations. Poggio's *History of Florence*, written in avowed imitation of Livy's manner, requires separate mention, since it exemplifies by its defects the weakness of that merely stylistic treatment which deprived so much of Bruni's, Carlo Aretino's, and Bembo's work of historical weight. A somewhat different criticism must be passed on the *Puettia*, a collection of humorous and indecent tales expressed in such Latinity as Poggio could command. This book is chiefly remarkable for its unsparing satires on the monastic orders and the secular clergy. It is also noticeable as illustrating the Latinizing tendency of an age which gave classic form to the lightest essays of the fancy. Poggio, it may be observed, was a fluent and copious writer in the Latin tongue, but not an elegant scholar. His knowledge of the ancient authors was wide, but his taste was not select, and his erudition was superficial. His translation of Xenophon's *Cyropædia* into Latin cannot be praised for accuracy. Among contemporaries he passed for one of the most formidable polemical or gladiatorial rhetoricians; and a considerable section of his extant works are invectives. One of these, the *Dialogue against Hypocrites*, was aimed in a spirit of vindictive hatred at the vices of ecclesiastics; another, written at the request of Nicholas V., covered the anti-pope Felix with scurrilous abuse. But his most famous compositions in this kind are the personal invectives which he discharged against Filelfo and Valla. All the resources of a copious and unclean Latin vocabulary were employed to degrade the objects of his satire; and every crime of which humanity is capable was ascribed to them without discrimination. In Filelfo and Valla Poggio found his match; and Italy was amused for years with the spectacle of their indecent combats. To dwell upon such literary infamies would be below the dignity of the historian, were it not that these habits of the early Italian humanists imposed a fashion upon Europe which extended to the later age of Scaliger's contentions with Scioppius and Milton's with Salmasius. The greater part of Poggio's long life was spent in attendance to his duties in the papal curia at Rome and elsewhere. But about the year 1452 he finally retired to Florence, where he was admitted to the burghership, and on the death of Carlo Aretino in 1453 was appointed chancellor and historiographer to the republic. He had already built himself a villa in Valdarno, which he adorned with a collection of antique sculpture, coins, and inscriptions. In 1455 he had married a girl of eighteen named Vaggia, of the famous Buondelmonte blood. His declining days were spent in the discharge of his honourable Florentine office and in the composition of his history. He died in 1459, and was buried in the church of Santa Croce. A statue by Donatello and

a picture by Antonio del Pollajuolo remained to commemorate a citizen who chiefly for his services to humanistic literature deserved the notice of posterity.

Poggio's works were printed at Basel in 1533, *ex ædibus Henrici Petri*. Dr Shepherd's *Life of Poggio Bracciolini* is a good authority on his biography. For his position in the history of the revival, students may consult Voigt's *Wiederbelebung des classischen Alterthums*, and Symonds's *Renaissance in Italy*. (J. A. S.)

POGY, a popular name for the fish *Clupea menhaden*, almost universally in use in the States of Maine and Massachusetts (see *MENHADEN*, vol. xvi. p. 10).

POINSOT, LOUIS (1777–1859), mathematician, was born at Paris January 3, 1777. In 1794 he became a scholar at the Polytechnic School, which he left in 1796 to act as a civil engineer. In 1804 he was appointed professor of mathematics at the Lyceum, in 1809 professor of applied mathematics and in 1816 examiner at the Polytechnic School. On the death of Lagrange in 1813, Poinsot was elected to his place in the French Academy; and in 1840 he became a member of the superior council of public instruction. In 1846 he was made an officer of the legion of honour; and on the formation of the senate in 1852 he was chosen a member of that body. He died at Paris, December 5, 1859. Poinsot's earliest work was his *Éléments de Statique*, in which he introduces the idea of statical couples and investigates their properties. In the *Théorie Nouvelle de la Rotation des Corps* he treats the motion of a rigid body geometrically, and shows that the most general motion of such a body can be represented at any instant by a rotation about an axis combined with a translation parallel to this axis, and that any motion of a body of which one point is fixed may be produced by the rolling of a cone fixed in the body on a cone fixed in space. The previous treatment of the motion of a rigid body had in every case been purely analytical, and so gave no aid to the formation of a mental picture of the body's motion; and the great value of this work lies in the fact that, as Poinsot himself says in the introduction, it enables us to represent to ourselves the motion of a rigid body as clearly as that of a moving point. Poinsot also contributed a number of papers on pure and applied mathematics to *Liouville's Journal* and to the *Journal* of the Polytechnic School.

POINT DE GALLE. See *GALLE*, vol. x. p. 40.

POINTE À PITRE, the principal port of the island of GUADELOUPE (q.v.).

POISONS. An exact definition of the word "poison" is by no means easy. There is no legal definition of what constitutes a poison, and the definitions usually proposed are apt to include either too much or too little. Generally, a poison may be defined to be a substance having an inherent deleterious property, rendering it capable of destroying life by whatever avenue it is taken into the system; or it is a substance which when introduced into the system, or applied externally, injures health or destroys life irrespective of mechanical means or direct thermal changes. In popular language, a poison is a substance capable of destroying life when taken in small quantity; but a substance which destroys life by mechanical means as, e.g., powdered glass, is not, strictly speaking, a poison.

The subject of toxicology forms one of the most important branches of MEDICAL JURISPRUDENCE (q.v.). The medical jurist should be familiar with the nature and actions of poisons, the symptoms which they produce, the circumstances which modify their working, the pathological results of their action, and the methods of combating these.

*Action of Poisons.*—Poisons may exert a twofold action. This may be either local, or remote, or both local and remote. The local action of a poison is usually one of corrosion, inflammation, or a direct effect upon the sensory or motor nerves. The remote actions of poisons are

usually of a specific character, though some writers group the remote effects of poisons under two heads, and speak of the common and the specific remote effects of a poison. The local action of a poison of the corrosive class is usually so well marked and obvious that the fact of the administration of a poison of this class is generally unmistakable. The same may be said, in a less degree, of the irritant poisons, especially the mineral irritants; but here the symptoms sometimes so closely simulate those of natural disease as to render the recognition of the administration of poison a matter of difficulty. Hence an accurate acquaintance with the remote specific effects of the various poisons is indispensable to the medical jurist. The class of poisons which has been administered or taken will thus be suggested to his mind by the observation of the symptoms; and not unfrequently the specific poison taken will be suspected. It is almost universally admitted that absorption of a poison is necessary for the production of its specific remote effects, and the old notion that a poison may kill, by its action through the nervous system, without absorption, is abandoned.

*Modifying Circumstances.*—The ordinary action of a poison may be greatly modified by the largeness of the dose, by the state of aggregation, admixture, or of chemical combination of the poison, by the part or membrane to which it is applied, and by the condition of the patient. Thus, for example, opium may be a medicine or a poison according to the dose in which it is given; and a dose of the drug which may be beneficial to an adult in certain states of the system may be fatal to a child, or to an adult when suffering from some forms of disease. All barium salts, again, are poisonous, except the quite insoluble sulphate. The simple cyanides, and many double cyanides, are highly poisonous; but yellow prussiate of potash, which is a double cyanide of iron and potassium, is almost without action upon the system. The part or tissue to which a poison is applied greatly affects the activity of a poison, owing to the varying rapidity with which absorption takes place through the cutaneous, mucous, and serous surfaces, and by the other tissues of the body. Curare, an arrow poison, may be swallowed in considerable quantity without appreciable result, whilst a minute quantity of the same substance introduced into a wound is speedily fatal. Idiosyncrasy has an important bearing in toxicology. Pork, mutton, certain kinds of fish, more especially shell fish so-called, and mushrooms have each produced all the symptoms of violent irritant poisoning, whilst other persons who have partaken of the same food at the same time have experienced no ill effects. Some persons are stated, on good authority, to be capable of taking with impunity such poisons as opium, corrosive sublimate, or arsenic, in enormous doses,—and this irrespective of habit, which is known to have such an influence in modifying the effects of some poisons, notably the narcotics. A tolerance of poisons is sometimes engendered by disease, so that a poison may fail to produce its customary effect. Thus, opium is tolerated in large quantities in tetanus, and in delirium tremens; and mercurial compounds may in some febrile affections fail to produce the usual constitutional effects of the metal. On the other hand, diseases which impede the elimination of a poison may intensify its effects.

The evidence that a poison has been administered is based upon the symptoms produced, on the appearances met with in the body after death, on the analysis of articles of food and drink, of excreta and ejecta, and of the organs of the body after death, and on physiological experiments made with substances extracted from the same articles. These physiological experiments are usually made upon animals, but in some cases, as for instance when aconite

has to be searched for, the physiological experiments must be made also upon the human subject. The evidence obtained from one or more of these sources, as compared with the properties or effects of various known poisons, will enable the medical jurist to form an opinion as to the administration or non-administration of a poison.

The symptoms exhibited by the patient during life rarely fail to afford some clue to the poison taken. Persons may, however, be found dead of whose history nothing can be learned. Here post-mortem appearances, chemical analysis, and, it may be, physiological experiments are all-important for the elucidation of the nature of the case.

Poisoning may be *acute* or *chronic*. The general conditions which should arouse a suspicion of acute poisoning are the sudden onset of serious and increasingly alarming symptoms in a person previously in good health, especially if there be pain in the region of the stomach, or, where there is complete prostration of the vital powers, a cadaveric aspect, and speedy death. In all such cases the aid of the analytical chemist must be called in either to confirm well-founded or to rebut ill-founded suspicions.

The mode of treatment to be adopted in the case of poisoned persons varies greatly according to the nature of the poison. The first indication, when the poison has been swallowed, is to evacuate the stomach; and this may usually be done by means of the stomach-pump when the poison is not of the corrosive class; or the stomach may be gently washed out by means of a funnel and flexible siphon-tube. In many cases emetics are valuable. Antidotes and counter-poisons may then be given. The former are such substances as chalk to neutralize the mineral acids and oxalic acid; the latter have a physiological counter-action, and are such as atropine, which is a counter-poison to morphia. These may usually be administered most effectively by hypodermic injection. The stomach may to a certain degree be protected from the injurious effects of irritants by the administration of mucilaginous drinks; alkaloids may be rendered sparingly soluble by means of astringent substances containing tannin; and pain may be relieved by means of opium, unless contra-indicated by the nature of the poison. The effects of the convulsant poisons, such as strychnine, may be combated by means of the inhalation of chloroform.

The classification of poisons is a matter of difficulty. Various attempts have been made to classify them scientifically, but with no signal success; and perhaps the best system is that which groups the various poisons according to the more obvious symptoms which they produce. Our knowledge of the more intimate action of poisons is still too imperfect to admit of any useful classification according to the manner in which they specifically affect the vital organs. Poisons may in the manner indicated be classified as (1) *Corrosives*, (2) *Irritants*, (3) *Neurotics*, and (4) *Gaseous Poisons*. The subject of poisonous food has already been treated under the heading MEDICAL JURISPRUDENCE (vol. xv. pp. 781-2).

#### 1. *Corrosives.*

The typical member of this class is corrosive sublimate, the soluble chloride of mercury. In it are included also the concentrated mineral acids (sulphuric, nitric, and hydrochloric); oxalic acid; the alkalies (potash, soda, and ammonia) and their carbonates; acid, alkaline, and corrosive salts of the metals (such as bisulphate of potash, alum, butter of antimony, and nitrate of silver); also carbolic acid.

The symptoms produced by the mineral acids and the alkalies are almost altogether referrible to local action; but some corrosive poisons, such as carbolic acid, produce,

besides a local action, remote and specific constitutional effects. The symptoms of corrosive poisoning are marked and unmistakable, except in infants. Immediately on swallowing the corrosive substance, an acid, caustic, or metallic burning sensation is experienced in the mouth, fauces, gullet, and region of the stomach, and this speedily extends over the whole belly; as a rule vomiting speedily follows. In the case of the mineral acids, and in oxalic acid poisoning, the vomit is so acid that if it falls upon a marble or concrete floor effervescence ensues. No relief follows the evacuation of the stomach. The ejected matters contain blood, and even fragments of the corroded walls of the alimentary canal. The belly becomes distended with gas, and horribly tender. High fever prevails. The mouth is found to be corroded. Death usually ensues within a few hours; or, if the patient survives, he or she may perish miserably, months after the poison was taken, through starvation consequent upon the gradual contraction of the gullet, brought about by its corrosion and subsequent healing.

The treatment of corrosive poisoning consists in very gently emptying and washing out the stomach by means of a soft siphon-tube. The stomach-pump cannot be used with safety in consequence of the weakening of the walls of the stomach by corrosion. Demulcents and opiates may be subsequently administered. After death from corrosive poisoning the walls of the stomach are found corroded, and even perforated.

1. *Corrosive Sublimate*.—Here all the signs and symptoms of corrosive poisoning are produced in their severest form. A grain or two of this poison may prove fatal. Fortunately there is an efficient antidote in white of egg, the albumen of which, if administered at once, renders the salt insoluble. The eggs should be divested of their yolks, beaten up with water, and given promptly, repeatedly, and abundantly, followed by emetics. Poisoning by corrosive sublimate may be followed by the specific toxic effects of mercury, such as salivation and tremor.

Workers in mercury, such as water-gilders, looking-glass makers, and the makers of barometers and thermometers, are apt to suffer from a peculiar form of shaking palsy, known as "the trembles," or mercurial tremor. This disease affects most frequently those who are exposed to mercurial fumes. The victim is affected with tremors when an endeavour is made to exert the muscles, so that he is unable, for instance, to convey a glass of water to the lips steadily, and when he walks he breaks into a dancing trot. The treatment consists in removal from the mercurial atmosphere, baths, fresh air, and the administration of iron and other tonics.

2. *Mineral Acids*.—These are oil of vitriol or sulphuric acid, aqua fortis or nitric acid, and spirit of salt or hydrochloric (muriatic) acid. These when taken in a concentrated form produce well-marked symptoms of corrosion. When they are diluted, the symptoms are those of an irritant poison. Nitric acid stains the mouth and skin of a yellow colour. The treatment consists in the administration of alkalis or their carbonates, chalk, whiting, or even uncoloured plaster scraped off the walls or ceiling, with the view of neutralizing the acid.

3. *Oxalic acid* is a vegetable acid. When taken in the state of concentrated solution it acts as a corrosive, but when diluted as an irritant. But it also exerts a specific effect, killing the patient by cardiac syncope not unfrequently within a few minutes. When a person after taking a crystalline substance, tasting strongly acid, dies within 15 or 30 minutes, after the manifestation of great weakness, small pulse, and failure of the heart's power, poisoning by oxalic acid is almost certain. The treatment consists in promptly administering an emetic, followed by chalk, whiting, or any substance containing carbonate of calcium. The alkaline carbonates are valueless, for the alkaline oxalates are almost as poisonous as oxalic acid itself.

4. *The Alkalies*.—Potash, soda, and their carbonates and sulphides produce symptoms resembling those of the mineral acids, except that purging is a usual accompaniment.

5. *Caustic acid* when taken in the form of a concentrated liquid acts as a corrosive, causing whitening and shrinking of all the animal membranes with which it comes in contact. The patient, however, becomes speedily comatose, the poison acting profoundly upon the great nervous centres. A curious phenomenon—black or dark green urine—is commonly observed after the administration of this poison. Saccharated lime-water, diluted and drunk freely, and a solution of sulphate of soda are perhaps the most useful remedies.

## 2. Irritant Poisons.

Irritant poisons are of two classes—metallic irritants, and vegetable and animal irritants, these latter being for convenience grouped together. Perhaps none of the irritants act purely as such, the irritant symptoms being usually accompanied by well-marked effects upon the nervous system. An irritant is a substance which causes inflammation of the part to which it is applied,—usually the alimentary canal. Arsenic is by far the most important of the metallic irritants. Other irritants are the moderately diluted acids, many metallic salts, such as those of antimony, lead, copper, zinc, and chromium. Elaterium, gamboge, aloes, colocynth, and croton oil are good examples of vegetable irritants; and cantharides of animal irritants. Animal and vegetable food when decomposed, or infested with certain organisms known as bacteria, may produce violent irritant symptoms. The symptoms produced by irritant poisons are usually more slow in their development than where a corrosive has been administered. Usually, after an interval, greater or less according to the specific nature of the irritant swallowed, a burning pain is felt in the mouth, throat, and gullet, with a sense of constriction of the parts, and followed by burning pain in the region of the stomach. This is increased, and not alleviated, by pressure, a mark which serves to distinguish the attack from one of ordinary colic. Nausea, vomiting, and thirst ensue, speedily followed by distension of the whole abdomen, which is exceedingly tender to the touch. Ordinarily the vomiting is followed by profuse diarrhoea. Should the poison not be speedily eliminated in the vomited and faecal matters, inflammatory fever sets in, followed by collapse; and death may ensue in a few hours.

There is danger of confounding irritant poisoning with some forms of natural disease, such as gastritis and gastric ulcer, colic, peritonitis, cholera, and rupture of the intestines.

1. *Arsenic* is a specific irritant poison. Almost all the compounds of this metal are poisonous. The term "arsenic" is, however, most commonly applied, not to the metal itself, but to its lower oxide, arsenious oxide, which is also known as *white arsenic*. By whatever channel arsenic is introduced into the system, it invariably affects specifically the stomach and intestines, causing congestion or inflammation. The common sources of arsenical poisoning are the taking of white arsenic, which causes acute poisoning, and the inhalation of dust from arsenical wall-papers and textile fabrics, whereby a chronic form of poisoning is induced.

The symptoms of acute arsenical poisoning do not come on, as in the case of corrosive poisoning, immediately after the poison is swallowed. There is usually an interval of half an hour or so before prominent symptoms supervene. Generally, after a feeling of faintness and depression, an intense burning pain is felt in the region of the stomach, with tenderness on pressure. Nausea and vomiting generally follow, increased by every act of swallowing. Unlike what occurs in ordinary vomiting, the pain and sickness are not relieved by the evacuation of the stomach. Vomiting is followed by purging, blood being frequently distinguishable in the evacuations. There is thirst, a feeble irregular pulse, and a perspiring clammy skin. The victim usually succumbs within eighteen to seventy-two hours; if he survives the latter period, good hopes may be entertained of his recovery. The treatment consists in the use of the stomach-pump, emetics, such as mustard and warm water, demulcents, and the free administration of magnesia emulsion and either freshly precipitated ferric hydrate or dialysed iron. Ferric hydrate, and the solution known as dialysed iron, have the property of rendering arsenious anhydride insoluble.

Chronic arsenical poisoning is usually accidental. The inhalation of arsenical vapours in factories, or of arsenical dust from green wall-papers and in the manufacture of artificial flowers, are common sources of this form of poisoning. Arsenic when thus slowly absorbed into the system produces congestion and inflammation of the mucous membranes, redness and irritation of the conjunctivæ, sore throat, a peculiar eruption of the skin, and diarrhoea. The treatment consists in removal from the poisoned atmosphere, and the administration of tonics.

Arsenic-eating, or the ability of some persons to take relatively large doses of arsenic habitually, is a well-established fact. The

cause of this singular immunity from the ordinary results of arsenic is quite unknown.

2. *Lead*.—The salts of lead, more especially the acetate (sugar of lead), are irritant poisons of no very great activity; and, though occasionally death ensues, recovery is the rule. Chrome yellow, or lead chromate, is a powerful irritant poison. All chromates are, indeed, irritant poisons.

Chronic lead poisoning is a much more common affection than acute irritant poisoning by lead. When lead in any form is slowly absorbed into the system, a peculiar affection results, known as saturnine poisoning, and characterized by two prominent symptoms—colic and paralysis. Workers in lead and its compounds, such as plumbers and painters, are frequently affected by this form of disease. Water, especially soft water or such as is contaminated with sewage, on being passed through leaden pipes or stored in leaden cisterns may become contaminated with lead to a dangerous extent. Acid liquids, such as cider, vinegar, &c., may also contain lead as an impurity. Potmen, who drink beer which has rested for some time in pewter vessels, are also the occasional victims of saturnine poisoning. Water which contains lead in a soluble form to the extent of more than one-tenth of a grain per gallon should not be used for drinking purposes. If more than this quantity be present, the water when placed in a white porcelain dish will become more or less dark in colour on the addition of a few drops of a solution of sulphuretted hydrogen.

The commonest manifestation of chronic lead poisoning is lead colic—a peculiar twisting and agonizing sensation around the navel, attended with obstinate constipation. This, like all forms of chronic lead poisoning, is almost invariably attended with a peculiar blue line on the margin of the gums, and when this is present the nature of the affection can scarcely be doubtful. The treatment consists in the free use of purgatives, opiates, and the internal use of potassium iodide, which favours the elimination of the metal through the urine. "Wrist-drop" or lead paralysis is also a common result of the ingestion of lead. It consists in a paralysis of the extensor muscles of the forearm, accompanied by a wasting of that structure. A dropping of the wrist is the result of this degeneration. Baths, the use of galvanism, and the administration of potassium iodide and tonics usually afford relief. Should, however, the patient in any form of lead poisoning be exposed for a lengthened period to the effects of the metal, degenerations of the liver, kidneys, and brain supervene, with fatal results.

In all cases of lead poisoning removal of the exciting cause is indispensable; the worker in lead must suspend his occupation for a time; the use of contaminated articles of food or drink must cease.

3. *Copper*.—The soluble salts of copper, such as blue vitriol (the sulphate) and verdigris (subcarbonate and subacetate), are emetic and irritant salts. Their emetic effects usually, but not invariably, secure their prompt rejection by the stomach. Occasionally fatal effects have resulted from their administration. Copper becomes accidentally mixed with articles of dietary in a variety of modes. It is also used for improving the colour of preserved fruits and vegetables. Its deleterious properties when thus used in minute quantities have been both asserted and denied. There is, however, a large body of evidence in favour of the at all events occasional poisonous effects of minute quantities of copper.

4. *Zinc salts and barium salts*, except the quite insoluble barium sulphate, are irritant poisons; and barium compounds act also upon the central nervous system.

5. *Chromates*, e.g., bichromate of potash, are violent irritants. Chrome yellow, or lead chromate, has already been mentioned.

6. *Phosphorus*.—Of the two chief forms of the element—the yellow or ordinary and the red or amorphous—the former only is poisonous. Rarely there is met with a chronic form of poisoning among workers in the material, arising from the inhalation of phosphorus vapours. Its special characteristic is a peculiar necrosis or death of the bony structure of the lower jaw. Acute phosphorus poisoning is more common. Phosphorus is used for tipping matches, and is also the basis of several vermin destroyers. When swallowed, phosphorus produces a variable amount of irritation and disturbance of the alimentary canal. There may be a burning sensation felt in the mouth, throat, and stomach, followed by vomiting. The vomited matters, and also the excreta, may be observed to be luminous in the dark. These symptoms usually subside, and for three or four days the person appears to have recovered his or her usual health. The liver then enlarges, and this and other structures undergo fatty degeneration; jaundice supervenes; and the patient dies in a few days in a semi-typhoid condition. Rarely there is recovery. Oil of turpentine is thought to be the best remedy. Most of the organs undergo fatty degeneration.

7. *Vegetable Irritants*.—These produce drastic purgative effects. Frequently the nature of the illness may be ascertained by the discovery of portions of the vegetable substance—recognizable by the microscope—in the matters ejected by the patient.

8. *Cantharides*.—The administration of CANTHARIDES (q.v.) is

followed by vomiting, purging, strangury, or even entire inability to pass the urine. In the ejecta portions of the shining elytra or wing-cases of the fly may often be recognized. There is often great excitement of the sexual proclivities. The active principle of the fly, cantharidin, may be extracted from suspected matters by means of chloroform, and the residue left after the evaporation of this blisters the lip or any tender mucous surface to which it is applied. Demulcent remedies, with opiate enemata and injections, afford the best relief by way of treatment.

### 3. Neurotics.

It is premature, for the present, to attempt a systematic division of this most important class, which embraces poisons so widely different in their actions as opium and strychnine. We at once proceed to details.

1. *Prussic or Hydrocyanic Acid*.—Hydrocyanic acid is one of the best-known poisons, and a very deadly one. In the pure state it is said to kill with lightning-like rapidity. It is met with in commerce only in a dilute state. In Great Britain two kinds of acid are commonly sold—the pharmacopoeial acid, containing 2 per cent. of anhydrous prussic acid, and Scheele's acid, containing 4 or 5 per cent. Less than a teaspoonful of the 2 per cent. acid has caused death. Given in fatal doses, the symptoms of prussic-acid poisoning set in with great rapidity; and, in consequence of the readiness with which the poison is absorbed from the stomach and diffused through the circulation, the onset of symptoms is reckoned by seconds rather than by minutes. Occasionally the victim may be able to perform a few voluntary actions before alarming symptoms are developed. There is first a very brief stage of difficult breathing, and slow action of the heart, with a tendency for the organ to stop in the state of dilatation. With widely-dilated pupils of the eye, the patient is then seized with violent irregular convulsive movements. The rhythm of the respiratory movements is disturbed, and the countenance becomes of a bluish cast. The patient now sinks to the ground with complete loss of muscular power; and the third or asphyxial stage is reached, in which there are slow gasping respirations, loss of pulse, and paralysis of motion. Death is frequently preceded by muscular spasms. The *foudroyant* character of the illness, and the speedy death of the patient, coupled with the peculiar odour of the acid in the breath and atmosphere around the body, seldom leave any doubt as to the nature of the case. The treatment consists in inhalation of the fumes of strong ammonia, drinks of warm and cold water alternately, friction of the limbs, and artificial respiration. The subcutaneous injection of atropine, which acts as a cardiac stimulant, may prove serviceable.

Other soluble cyanides, more especially cyanide of potassium, a salt largely used in photography and in the arts, are equally poisonous with hydrocyanic acid. See PRUSSIC ACID.

2. *Opium*.—In consequence of the extent to which OPIUM (q.v.), its preparations, and its active alkaloid morphia are used for the relief of pain, poisoning by opium is of frequent occurrence. It is largely used by suicides; and children, being very susceptible to its influence, frequently die from misadventure after administration of an overdose of the drug. The ordinary preparations of opium are the drug itself, which is the inspissated juice of the Oriental poppy, and the tincture, commonly known as laudanum. Opium contains a variety of more or less active principles, the chief of which is the alkaloid morphia, which is present in good opium to the extent of about 10 per cent. in combination with meconic acid, which is physiologically inactive. Opium is largely used by Eastern nations for smoking, and there is great discrepancy of opinion as to the extent to which opium smoking is deleterious. The preponderance of opinion is in favour of the view that opium smoking is a demoralizing, degrading, and pernicious habit, and that its victims are sufferers both in body and mind from its use.

The first symptom of the administration of a poisonous dose of opium is a state of exaltation—which may not, however, be well-marked—soon passing into a second stage, in which the symptoms are those of congestion of the brain. The countenance is suffused and of a bluish cast, known as cyanosis, due to imperfect aeration of the blood; the pupils of the eyes are minutely contracted, the skin dry and warm, and the breathing slow, laboured, and becoming stertorous. The patient is apparently unconscious, but may be roused by shaking, or by shouting into the ear. When this has taken place, the breathing becomes more natural, and the skin less cyanosed. If he be left alone there is a speedy relapse into a state of insensibility. If effective treatment be not adopted, a third stage of prostration supervenes, in which there is profound coma, and it may be impossible to arouse the patient. The pupils of the eyes are now contracted to the size of pin-points. Breathing is slow, shallow, and intermittent. The countenance is at once pallid and cyanosed, the skin bathed in perspiration. The pulse becomes more rapid with increased feebleness, and at length all signs of it are lost, until death supervenes.

The treatment consists in the use of the stomach-pump. Emetics

are usually inoperative. After this the patient must be kept awake by walking him about, applying cold and warm douches alternately to the chest, shouting into the ears, flicking the hands and feet with damp towels, and the application of the galvanic current. Circulation should be promoted by friction of the limbs and trunk. Strong infusion of coffee, ammonia, and alcoholic stimulants may be freely administered. As a last resort when the breathing intermits, artificial respiration may be performed. The hypodermic injection of full doses of atropine has proved of marked benefit,—atropine and morphia being to a certain extent counter-poisons.

Opium is a drug to which its victims may become habituated by the use of gradually increasing doses; and the practice of opium-eating, as it is termed, is a pernicious one. An atrophied condition of the body usually results. The only remedy is abstinence from the drug.

3. *Strychnine and Strychnine-yielding Plants*.—The alkaloids strychnine and brucine, as well as all the plants in which they are found, all act in the same manner, being highly poisonous, and causing death after spasms of a severe character. Strychnine was first extracted from the seeds of *Strychnos Nux-Vomica* in 1819, by Pelletier and Caventou. It exists in larger quantity in other species of the genus *Strychnos*, and notably in *Strychnos Ignatii*. From the bark of *Strychnos Nux-Vomica*, known as false Angostura bark, another alkaloid, *brucine*, is also extracted. This bark was at one time wrongly supposed to be the bark of *Brucina anti-dysenterica*; hence the name *brucina* or *brucine*. Its effects are similar to those of strychnine, but its physiological activity is not so great. Many vermin-killers contain strychnine as their active ingredient.

Strychnine, and all substances containing that alkaloid, produce their effects within a very few minutes—usually within ten or fifteen minutes. The patient complains of stiffness about the neck, and his aspect exhibits terror. There is an impression of impending calamity or death. Very speedily the head is jerked back, the limbs extended, the back arched (opisthotonos), so that the body may rest on the head and heels only. The mouth is drawn; and the condition is one known as tetanus. In a few moments these symptoms pass off, and there is complete relaxation of the spasm. The spasmodic condition speedily returns, and is brought about by the slightest touch or movement of the patient. Accessions and remissions of the tetanic state ensue rapidly till the patient succumbs, usually within half an hour of the administration of the poison. The best treatment is to put, and keep, the patient under the influence of chloroform till time is given for the excretion of the alkaloid, having previously given a full dose of chloral hydrate.

4. *Aconite Poisoning*.—The ordinary blue rocket, wolfsbane, or monkshood, *Aconitum Napellus*, and an alkaloid extracted from it, aconitine, are perhaps the most deadly of known poisons. One-sixteenth of a grain of aconitine has proved fatal to a man. All the preparations of aconite produce a peculiar burning, tingling, and numbness of the parts to which they are applied. When given in large doses they produce violent vomiting, as a rule, more or less paralysis of motion and sensation, and great depression of the heart, usually ending in death from syncope. Intelligence remains unaffected till almost the last. The treatment consists in the hypodermic injection of tincture of foxglove (*Digitalis*) or its active principle digitalin, which is a counter-poison in its action upon the heart. The root of aconite has been eaten in mistake for that of horse-radish.

5. *Belladonna*.—The belladonna or deadly nightshade, *Atropa Belladonna*, contains an alkaloid, atropine, which is largely used by oculists to procure dilatation of the pupils of the eye. The bright scarlet berries of the plant have been eaten by children, who are attracted by their tempting appearance. Belladonna produces dilatation of the pupils, rapid pulse, hot dry flushed skin, with an eruption not unlike that of scarlatina, soreness of the throat, with difficulty of swallowing, intense thirst, and gay mirthful delirium. The treatment consists in evacuation of the poison by means of the stomach-pump, and the hypodermic injection of morphia as a counter-poison.

#### 4. Gaseous Poisons.

The effects of these are varied,—some of them acting as irritants, while others have a specific effect, apparently in consequence of their forming chemical compounds with the red pigment of the blood, and thus destroying its capability of acting as a carrier of oxygen.

1. *Chlorine and bromine* act as powerful irritants. They provoke spasm of the glottis when inhaled, and subsequently induce inflammation of the respiratory mucous membrane, which may prove speedily fatal. Inhalation of diluted ammonia vapour is the best remedy.

2. *Hydrochloric or muriatic acid gas and hydrofluoric or fluoric acid gas* are irritating and destructive to life. The former is more destructive to vegetable life than even chlorine. They are emitted

in many processes of manufacture, and especially in the manufacture of carbonate of soda from common salt by Le Blanc's process, in the salt-glazing of earthenware, and in the manufacture of artificial manures.

3. *Sulphurous Acid Gas*.—The gas given off by burning sulphur is most suffocating and irritating. Its inhalation, even in a highly diluted state, may cause speedy death from spasmodic closure of the glottis.

4. *Nitrous vapours*, or gaseous oxides of nitrogen (except nitrous oxide), are given off from galvanic batteries excited by nitric acid; also in the process of etching on copper. They produce, when diluted, little immediate irritation, but are exceedingly dangerous, setting up extensive and fatal inflammation of the lungs.

5. *Ammonia gas* is highly irritant, but does not often prove fatal.

6. *Carbonic acid gas* is heavier than atmospheric air, is totally irrespirable when pure, and is fatal when present in large quantities in respired air. It is given off from burning fuel, accumulates in pits and wells as choke-damp, and constitutes the deadly after-damp of coal-mines. It is also formed during alcoholic fermentation, and hence accumulates in partially filled vats in which fermented liquors are stored. When it is breathed in a concentrated state, death is almost instantaneous. Persons descending into wells foul with this gas sink down powerless, and are usually dead before they can be removed from the vitiated atmosphere. In these cases there is true asphyxia; but carbonic acid is also a narcotic gas. Persons exposed to an atmosphere partially composed of this gas, but not long enough to produce fatal results, are affected with stertorous breathings, oppression, flushed face, prominent eyes, swollen tongue, and feeble pulse. The proper treatment is removal from the foul atmosphere, alternate cold and tepid douches to the chest, friction of the limbs and trunk, and artificial respiration. When animation is restored the patient should be put to bed and kept quiet, but should be carefully watched in case of relapse.

7. *Carbonic oxide gas* is given off by burning charcoal and other forms of fuel, mixed with carbonic acid. The poisonous effects of charcoal fumes are perhaps due rather to the more poisonous carbonic oxide than to the less poisonous carbonic acid. An atmosphere containing less than 1 per cent. of carbonic oxide would doubtless be fatal if breathed for many minutes. Carbonic oxide forms with hæmoglobin, the red pigment of the blood, a bright scarlet compound. The compound is very stable, and the oxide cannot be displaced by atmospheric oxygen. Hence the blood after death from the inhalation of carbonic oxide is of a bright arterial hue, which it retains on exposure to air.

8. *Coal-gas* acts as an asphyxiant and narcotic. The appearances met with after death—more especially the fluid state of the blood—are similar to those observed after death from carbonic oxide gas, which is a constituent of coal-gas, and to which the chief effect of coal-gas may be due.

9. *Sulphuretted hydrogen gas* is highly poisonous by whatever channel it gains access to the body. In a concentrated form it produces almost instant death from asphyxia. Even in a diluted state it produces colic, nausea, vomiting, and drowsiness. This may pass into insensibility with lividity and feeble respiration. The skin is cold and clammy, or bathed in perspiration. The red blood corpuscles are disintegrated. The treatment consists in removal from the contaminated atmosphere, friction to the surface of the body, warmth, and the administration of stimulants. The inhalation of chlorine gas has been recommended on chemical grounds; but it must be remembered that chlorine is itself poisonous.

10. *Anæsthetics*.—Nitrous oxide, or laughing gas, and the gases or vapours of other anæsthetic substances, such as chloroform, produce death by asphyxia, and perhaps otherwise. Obviously, as a rule, medical assistance is at hand. The treatment consists in artificial respiration, and the use of galvanic current.

11. *Vapours of Hydrocarbons*.—The volatile vapours of the natural hydrocarbons known as benzoline, petroleum, &c., are poisonous when inhaled for lengthened periods. (T. S.\*)

POISSON, SIMÉON DENIS (1781–1840) a celebrated French mathematician, was born at Pithiviers in the department of Loiret, on the 21st June 1781. His father, Siméon Poisson, served as a common soldier in the Hanoverian wars; but, disgusted by the ill treatment he received from his patrician officers, he deserted. About the time of the birth of his son Siméon Denis he occupied a small administrative post at Pithiviers, and seems to have been at the head of the local government of the place during the revolutionary period. The infant Poisson was put out to nurse, and concerning his nursing Arago relates the following story, which he had from its hero himself. One day the anxious father went to visit his son, but found that the nurse had gone to the fields. Impatient.

he broke into the cottage, and there saw, with painful astonishment, the object of all his hopes suspended by a small cord to a nail fixed in the wall. This was a precaution on the part of the peasant nurse to prevent her charge from perishing under the teeth of the carnivorous and unclean animals that circulated in the house. Poisson, in telling the story, added—"A gymnastic effort carried me incessantly from one side of the vertical to the other; and it was thus, in my tenderest infancy, that I made my prelude to those studies on the pendulum that were to occupy so much of my maturer age."

Having survived the perils of infancy, and received the elements of his education (reading and writing) from his father, the question arose what calling he was to follow. It was at first suggested that he should be made a notary; but the family council, with amusing irony, decided that this profession made too great demands upon the intellect, and surgery was preferred. He was sent to an uncle who exercised this art at Fontainebleau, and forthwith began to take lessons in bleeding and blistering, then the leading branches of a surgeon's practice. To train him in the former, he was set to prick the veins of cabbage leaves with a lancet, but made little progress; how he sped in the latter he himself relates as follows:—"Once my uncle sent me, with one of my comrades, M. Vanneau, now established in the colonies, to put a blister on the arm of a child; the next day, when I presented myself to remove the apparatus, I found the child dead; this event, very common they say, made the most profound impression upon me; and I declared at once that I would never be either physician or surgeon. Nothing could shake my resolution, and they sent me back to Pithiviers." Here accident and the bent of nature solved the problem that had passed the wisdom of the family council. The elder Poisson, being a Government official, received a copy of the *Journal de l'École Polytechnique*; the son read it, and soon began unaided to solve the problems propounded there from time to time; and thus his mathematical talent was discovered. He was sent to the École Centrale of Fontainebleau, and was fortunate in having a kind and sympathetic teacher, M. Billy, who, when he speedily found that his pupil was becoming his master, devoted himself to the study of higher mathematics in order to follow and appreciate him, and predicted his future fame by the punning quotation from Lafontaine<sup>1</sup>—

"Petit Poisson deviendra grand  
Pourvu que Dieu lui prête vie."

At the age of seventeen the young provincial, less remarkable for the elegance of his attire than for the profundity of his scientific knowledge, came up to Paris to undergo the entrance examination for the Polytechnic School. He passed first in his year, and immediately began to attract the notice of the professors of the school, who, seeing his obvious genius, excused him from the ordinary drudgery of the curriculum, and left him free to follow the studies of his predilection. The wisdom of this course was soon proved; for, in 1800, less than two years after his entry, he published two memoirs, one on Bezout's method of elimination, the other on the number of integrals of an equation of finite differences. The latter of these memoirs was examined by Lacroix and Legendre, who recommended that it should be published in the *Recueil des Savants Étrangers*, an unparalleled honour for a youth of eighteen. This success at once procured for Poisson an entry into the Parisian scientific society of the day, the like of which for brilliancy has never elsewhere been seen. Its two kings both patronized him. Lagrange, whose lectures on the theory of functions

<sup>1</sup> This prediction is sometimes attributed to Laplace.

he attended at the Polytechnic School, early recognized his talent, and became his friend; while Laplace, in whose footsteps Poisson followed, regarded him almost as his son. The rest of his career, till his death on the 25th of April 1840, was almost entirely occupied in the composition and publication of his many works, and in discharging the duties of the numerous educational offices to which he was successively appointed. Immediately after finishing his course at the Polytechnic School he was appointed répétiteur there, an office which he had discharged as an amateur while still a pupil in the school; for it had been the custom of his comrades often to resort to his room after an unusually difficult lecture to hear him repeat and explain it. He was made professeur suppléant in 1802, and full professor in succession to Fourier in 1806. In 1808 he became astronomer to the Bureau des Longitudes; and, when the Faculté des Sciences was instituted in 1809, he was appointed Professeur de la Mécanique Rationnelle. He further became member of the Institute in 1812, examiner at the military school at St Cyr in 1815, leaving examiner at the Polytechnic in 1816, councillor of the university in 1820, and geometer to the Board of Longitude in succession to Laplace in 1827.

In 1817 he married Mademoiselle Nancy de Bardi, daughter of a French family which had emigrated to England, and by her he had two sons and two daughters.

Poisson was a simple-minded affectionate man. This is seen in the close relations which he kept up with his old teacher M. Billy, who ardently loved and admired his former pupil, and whose presence at the Institute was a well-known sign that Poisson was to read a paper there. Although he never returned to Pithiviers after his entry into the Polytechnic School, he corresponded constantly with his parents, more especially with his mother; and he regularly sent copies of his memoirs to his father, who read and re-read with unwearied patience the parts of them within his comprehension. His tastes seem to have been of the simplest description; he took little exercise, and he had more than a Frenchman's horror of travelling. Arago says that he only travelled once, and that by medical prescription, disguised under the form of some mission connected with the Polytechnic School, and that, after devoting his savings to the purchase of a beautiful farm in the department of Seine-et-Marne, he never so much as visited it.

It is probable that his simplicity of character had much to do with his passing apparently quite undisturbed through the stormy time in which he lived, a period in which many men of mark lost their heads, and few such escaped without loss of office and fortune. His father, whose early experiences led him to hate aristocrats, bred him in the stern creed of the first republic. Throughout the empire Poisson faithfully adhered to the family principles, and refused to worship Napoleon. Napoleon, however, never interfered with Poisson's promotion. He said once himself that he never did anything uselessly, certainly never committed a useless crime; and he was wise enough to see that nothing was to be gained by persecuting the harmless academician, whose fame he doubtless regarded like that of the other savants of France as an apanage of his own glory. When the Bourbons were restored, his hatred against Napoleon led him to become a Legitimist—a conclusion which says more for the simplicity of his character than for the strength or logic of his political creed.

He was faithful to the Bourbons during the Hundred Days, in fact was with difficulty dissuaded from volunteering to fight in their cause. After the second restoration his fidelity was recognized by his elevation to the dignity of baron in 1825; but he never either took out his

diploma or used the title. The revolution of July 1830 threatened him with the loss of all his honours; but this disgrace to the Government of Louis Philippe was adroitly averted by Arago, who, while his "revocation" was being plotted by the council of ministers, procured him an invitation to dine at the Palais Royal, where he was openly and effusively received by the citizen king, who "remembered" him. After this, of course, his degradation was impossible; he was left in undisturbed possession of all his well-earned appointments; and seven years later he was made a peer of France, not for political reasons, but as a representative of French science.

As a teacher of mathematics Poisson is said to have been more than ordinarily successful, as might have been expected from his early promise as a répétiteur at the Polytechnic School. As a scientific worker his activity has rarely if ever been equalled. Notwithstanding his many official duties, he found time to publish more than three hundred works, several of them extensive treatises, and many of them memoirs dealing with the most abstruse branches of pure and applied mathematics. There are two remarks of his, or perhaps two versions of the same remark, that explain how he accomplished so much: one, "La vie n'est bonne qu'à deux choses—à faire des mathématiques et à les professer;" the other, "La vie c'est le travail."

A list of Poisson's works, drawn up by himself, is given at the end of Arago's biography. A lengthened analysis of them would be out of place here, and all that is possible is a brief mention of the more important. There are few branches of mathematics to which he did not contribute something, but it was in the application of mathematics to physical subjects that his greatest services to science were performed. Perhaps the most original, and certainly the most permanent in their influence, were his memoirs on the theory of electricity and magnetism, which virtually created a new branch of mathematical physics. They have been already repeatedly referred to in the articles ELECTRICITY and MAGNETISM (q.v.). Next (perhaps in the opinion of some first) in importance stand the memoirs on celestial mechanics, in which he proved himself a worthy successor to Laplace. The most important of these are his memoirs "Sur les inégalités séculaires des moyens mouvements des planètes," "Sur la variation des constantes arbitraires dans les questions de mécanique," both published in the *Journal of the Polytechnic School*, 1809; "Sur la libration de la lune," in *Connais. d. Temps*, 1821, &c.; and "Sur la mouvement de la terre autour de son centre de gravité," in *Mém. d. l'Acad.*, 1827, &c. In the first of these memoirs Poisson discusses the famous question of the stability of the planetary orbits, which had already been settled by Lagrange to the first degree of approximation for the disturbing forces. Poisson showed that the result could be extended to a second approximation, and thus made an important advance in the planetary theory. The memoir is remarkable inasmuch as it roused Lagrange, after an interval of inactivity, to compose in his old age one of the greatest of his memoirs, viz., that "Sur la théorie des variations des éléments des planètes, et en particulier des variations des grands axes de leurs orbites." So highly did he think of Poisson's memoir that he made a copy of it with his own hand, which was found among his papers after his death. Poisson made important contributions to the theory of attraction. His well-known correction of Laplace's partial differential equation for the potential was first published in the *Bulletin de la Société Philomatique*, 1813. His two most important memoirs on the subject are "Sur l'attraction des sphéroïdes" (*Connais. d. Temps*, 1829), and "Sur l'attraction d'un ellipsoïde homogène" (*Mém. d. l'Acad.*, 1835). In concluding our selection from his physical memoirs we may mention his memoir on the theory of waves (*Mém. d. l'Acad.*, 1825).

In pure mathematics, his most important works were his series of memoirs on definite integrals, and his discussion of Fourier's series, which paved the way for the classical researches of Dirichlet and Riemann on the same subject; these are to be found in the *Journal of the Polytechnic School* from 1813 to 1823, and in the *Memoirs of the Academy* for 1823. In addition we may also mention his essay on the calculus of variations (*Mém. d. l'Acad.*, 1833), and his memoirs on the probability of the mean results of observations (*Connais. d. Temps*, 1827, &c.).

Besides his many memoirs Poisson published a number of treatises, most of which were intended to form part of a great work on mathematical physics, which he did not live to complete. Among these may be mentioned his *Traité de Mécanique*, 2 vols. 8vo, 1811 and 1823, which was long a standard work; *Théorie Nouvelle de l'Action Capillaire*, 4to, 1831; *Théorie Mathématique de*

*la Chaleur*, 4to, 1825; *Supplément to the same*, 4to, 1837; *Recherches sur la probabilité des jugements en matières criminelles*, &c. 4to, 1837, all published at Paris.

Enough has been said to establish Poisson's fertility as a writer on mathematical subjects, and the question naturally suggests itself, What is his rank among the mathematicians of all ages? Since his own age was more productive of great mathematicians than any other the world has yet seen, it is natural to compare him with his contemporaries, chief among whom were Lagrange and Laplace. In so doing we see at once that, although we cannot seat him alongside of these mighty sovereigns, yet it is impossible to deny him the nearest rank to them in the temple of mathematical fame. In confirmation of this judgment, we cannot do better than quote one of them—"I am old," said Lagrange to Poisson one day; "during my long intervals of sleeplessness I divert myself by making numerical approximations. Keep this one; it may interest you. Huygens was thirteen years older than Newton, I am thirteen years older than Laplace; D'Alembert was thirty-two years older than Laplace, Laplace is thirty-two years older than you." Arago, who gives this story, justly remarks that no more delicate way could be conceived of intimating to Poisson his admission into the inner circle of the fraternity of mathematical genius. (G. CH.)

POITIERS, a town of France, formerly the capital of Poitou, and now the chief town of the department of Vienne, lies 206 miles south-west of Paris on the railway to Bordeaux, at the junction of the Boivre with the Clain (a tributary of the Loire by the Vienne), and occupies the slopes and summit of a plateau which rises 130 feet above the level of the streams by which it is surrounded on three sides. The town is picturesque; and its narrow, ill-paved, irregular, and deserted streets with their ill-built houses are interesting for certain remains of ancient architecture and the memories of great historical events. Blossac park, named after the intendant of the "generality" of Poitiers (1751-1786), and situated on the south side of the town, and the botanic garden on the north-east, are the two principal promenades. Besides being the see of a bishopric, which comprises the departments of Vienne and Deux-Sèvres, Poitiers possesses a court of appeal, national faculties of law, literature, and science, a free faculty of Catholic theology, a school of artillery, and numerous learned societies, of which the most celebrated is that of the "Antiquaires de l'Ouest" dating from 1834. Though not strictly a commercial or industrial town, it is the centre from which railways branch out to Tours, Angers, Niort, Angoulême, Limoges, and prospectively to Châteauroux and Nantes. Up till 1857 it contained the ruins of a Roman amphitheatre more extensive than that of Nîmes; remains of Roman baths, constructed in the 1st and demolished in the 3d century, were laid bare in 1877; and in 1879 a pagan burial place and the tombs of a number of Christian martyrs were discovered on the heights to the south-east—the names of some of the Christians being preserved in paintings and inscriptions. Not far from these tombs is a huge dolmen (the "Pierre Levée"), 22 feet long, 16 feet broad, and 6 or 7 feet high, around which used to be held the great fair of St Luke.

The cathedral of St Peter, begun in 1162 by Eleanor of Guienne on the ruins of a Roman basilica, and well advanced at the time of her death in 1204, is a building after the Plantagenet or Angevin style. Its length is 303 feet, its width 128, and the keystone of the central vaulted roof is 89 feet above the pavement. There is no apse, and the exterior generally has a heavy appearance. The principal front has unfinished side-towers 105 and 110

feet in height, begun in the 13th century. Most of the windows of the choir and the transepts preserve their stained glass of the 12th and 13th centuries; the end window, which is certainly the first in the order of time, contains the figures of Henry II of England and Eleanor. The choir stalls, carved between 1235 and 1257, are the oldest in France. The church of St Jean (originally a baptistery) near the cathedral is the most ancient Christian monument in the country. The church of St Hilaire was erected at the close of the 4th century over the tomb of the celebrated bishop. At first an unpretending oratory, it was rebuilt on a larger scale by Clovis, and afterwards became, in the 10th, 11th, and 12th centuries, a sumptuous collegiate church, of which the nave was flanked by triple aisles and surmounted by six cupolas. Great damage was done to it in the wars of religion and the French Revolution. The confessional or oratory under the choir contains the relics of St Hilary and a Christian sarcophagus of the 4th century. The church of St Radegonde, a great resort of pilgrims, commemorates the consort of Hlothar I. (c. 550), and preserves in its crypt, not only the tomb of Radegonde, who founded at Poitiers the abbey of the Holy Cross, but those of St Agnes and St Discolia. The church is in the Angevin style; the choir is of the 11th, and the nave of the 13th century. Notre Dame la Grande, which dates from the close of the 11th century, and represents a collegiate church one or two hundred years older, has a richly sculptured Romanesque façade. The first stone of the church of Moutierneuf (*Monasterium Novum*) was laid in 1077 by William, duke of Aquitaine and count of Poitiers, who is buried within its walls; and the choir (afterwards in the 13th century modified by the erection of a "lantern") was solemnly consecrated by Urban II. in 1096. Mutilated about 1640 and during the Revolution, the building was partly restored between 1850 and 1860. The tower of St Porchaire, a precious remnant of 11th-century architecture, has been restored in the present generation under the auspices of the Antiquaires de l'Ouest and the French archaeological society. Other churches of interest are the Chapel of the Lycée, that of the Sisters of the St Croix, and the old church of the Jesuits.

Among the secular buildings the first place belongs to the law courts, formerly the palace of the dukes of Aquitaine and counts of Poitiers, and rebuilt between the 12th and the 15th century. The Salle des Pas Perdus forms a fine nave 160 feet long by 56 feet wide, with a vaulted wooden roof. The southern wall is the work of Duke Jean de Berri, brother of Charles V.; above its three vast fireplaces are mullioned windows filled with stained glass. The Maubergeon tower attached to the palace represented the feudal centre of all the lordships of the countship of Poitiers. The prévôté or provost's mansion, now occupied by a communal school, has a fine façade of the 15th century. In the new hôtel de ville, erected between 1869 and 1876, are museums of archaeology, natural history, and painting. The museum of the Antiquaires de l'Ouest occupies the chapel and the great hall of the old university, now located in the old hôtel de ville; it is a valuable collection comprising Roman antiquities, Merovingian sculptures, medals, a fine Renaissance fireplace, &c. The building devoted to the faculties of law, science, and literature (of which the first dates from 1431) also contains the library (35,000 printed volumes and 300 MSS.). The municipal records are very rich in charters of Eleanor of Aquitaine, Philip Augustus, Alphonse of Poitiers, &c. Convents and religious educational establishments are numerous in the town. The population of Poitiers in 1881 was 34,355.

Poitiers, called Limonum at the time of the Roman conquest,

then took the name of its Gallic founders the Pictones or Pictavi. Christianity was introduced in the 3d century, and the first bishop of Poitiers, from 350 to 367, was St HILARIUS (q.v.). Fifty years later the city had fallen into the hands of the Arian Visigoths, and become one of the principal residences of their kings. Alaric, one of their number, was defeated by Clovis at Vouillé not far from Poitiers in 507. This was the first occasion on which the peoples of northern and southern Gaul met in conflict in the neighbourhood of the town which was destined to see them so frequently join battle. By his victory in 732 over the Mohammedans at Moussais-la-Bataille in this region, Charles Martel proved the saviour of Christendom. Under the Carolingians, Poitiers was dependent on the crown and afterwards on the duchy of Aquitaine. Eleanor of Guienne, after her divorce from Louis VII., carried it to her new husband Henry Plantagenet. She frequently resided in the city, which she embellished and fortified, and in 1199 entrusted with communal rights. Philip Augustus, having confiscated the Continental territories of John of England, united Poitou to the French crown; Louis VIII. made it an apanage for his son Alphonse of Poitiers, who afterwards became count of Toulouse. At a plenary court held in 1241 in the great hall of the palais de justice, Alphonse received the homage of his numerous vassals. After his death in 1271 Poitou reverted to the crown. But, King John having been defeated and made prisoner in the disastrous battle of Poitiers (fought 4 miles E. of the town on the hillside of Nouaille, 19th September 1356), Poitou was recognized as an English possession by the treaty of Brétigny (1360). Nine years later it was recovered by Duguesclin; and it became in succession the apanage of Jean de Berri, brother of king Charles VI., and of the dauphin, afterwards Charles VII. It was at Poitiers that the latter was proclaimed king (1423); and he removed thither the parlement and university of Paris, which remained in exile till the English withdrew from the capital in 1436. During this interval (1429) Joan of Arc was subjected to a formal inquest by the doctors of the university. Calvin had numerous converts at Poitiers. Of the violent proceedings which attended the wars of religion the city had its share. In 1569 it was defended by Count du Lude against Coligny, who after an unsuccessful bombardment retired from the siege at the end of seven weeks.

POITOU, one of the old provinces of France, which also formed one of the great military governments of the kingdom, was bounded N. by Brittany, Anjou, and Touraine; S. by Angoumois and Aunis; E. by Touraine, Berri, and Marche; and W. by the ocean. It was divided into Lower Poitou, which corresponded to the modern department of La Vendée, and Upper Poitou, now split into the departments of Deux-Sèvres and Vienne. The principal towns in Upper Poitou were Poitiers the capital, Mirebeau, Châtelleraut, Richelieu, Loudun, Thouars, Mauléon, Parthenay, Niort, &c.; and in Lower Poitou Fontenai-le-Comté, Maillezais, Luçon, and Roche-sur-Yon. Île d'Yeu or Île-Dieu and Noirmoutier belonged to the province. Ecclesiastically Poitou was distributed among the dioceses of Poitiers, Luçon, and La Rochelle; for the administration of justice, it was attached to the parlement of Paris.

Poitou (Poictou, Pictavia) takes its name from the Pictones or Pictavi, a Gallic nation mentioned by Cæsar, Strabo, and Ptolemy, and described by Strabo as separated from the Namnetes on the north by the Loire. It formed part of the territory known as AQUITANIA (q.v.). For the history see POITIERS.

POKER, a game at cards,—probably a development of *il frusso* (played in Italy in the 15th century). A similar but less simple game, called *primiera*, was also played in Italy in the 16th century, whence under the name of *primero* it travelled to Spain. *La prime* is mentioned by Rabelais (16th century); and later the game of prime elaborated was played in France under the name of *l'ambigu* or *le meslé*. Prime was also played in England in the 16th century; and later a bastard kind of prime, called post and pair, was much played in the west of England. Gleek had some points of resemblance to these games. The more modern game of brag is only post and pair with variations. Poker (originally played in America) may be described as developed brag, though in some respects it "throws back" to the parent games post and pair, l'ambigu, and primero.

other players to go out of the game, may be resorted to occasionally with success; but, as a rule, the player who goes in best will come out best. When about to bluff draw only one card or no cards. 9. A straight or higher hand may be backed freely, but the other players are more likely to go on staking if the raise is by small sums at a time. The only general rule that can be given is to change the raising tactics pretty frequently.

*Laws of Poker.*—These vary considerably. The following are based on "the American Hoyle." *Determination of Deal.*—1. One card is given to each player. Lowest has the deal. Ace is lowest. Ties of lowest card have one card each given again. The deal goes in rotation to the left of the last dealer. *Shuffling, Cutting, and Dealing.*—2. Any one may shuffle, the dealer last. 3. The player to the dealer's right cuts at least four cards. The dealer reunites the packets. If before the deal a card is exposed, there must be a fresh cut. A blank card is usually placed under the pack to prevent exposure of the bottom card. 4. The dealer must deal from the top of the pack, one card to each player in rotation, beginning to his left. 5. If the dealer deals without having the pack cut, or shuffles after it is cut, or misses a hand, or gives too many or too few cards to any player (but see Law 6), or exposes a card in dealing, he forfeits an ante to the pool and deals again. The forfeit does not raise the other players, and the dealer must still make his first ante good when it comes to his turn, or go out of the game. (Some players merely require a fresh deal without any forfeit, and some require a player to take the card dealt him if only one card is exposed.) *Filling the Hands.*—6. If a player, after lifting any of his cards, is found to have too many or too few cards, he must go out of the game. (Some players give a hand with only four cards the option of going in.) 7. If, when drawing to fill, the dealer gives a player too many or too few cards, and the player lifts any of them, he must go out of the game. If the error is discovered before lifting, it can be rectified,—in the case of too many cards by withdrawing the superfluous ones, in the case of too few cards by filling from the top of the pack. 8. If, when drawing to fill, a card is exposed, it must be placed at the bottom of the pack, and the top card given instead (sometimes the top card after all the other players are served). 9. Cards thrown out must be placed face downwards in the middle of the table before any are drawn; otherwise the player is liable to the penalty for holding too many cards (Law 6). 10. Any player before taking up his filled hand may ask how many cards the dealer drew. *Chipping.*—11. If all the players pass without chipping to fill, the dealer takes back his ante, and the deal passes. If, after filling, no one before the dealer raises, the dealer takes the pool. 12. If a player chips with more or less than five cards (but see note to Law 6), he must go out of the game. But, if all the other players have gone out of the game before the discovery is made, there is no penalty. 13. A player who passes or throws up cannot come in again. 14. Players are bound to put up distinctly the amount they chip, separate from their other chips. *Aftercomers.*—15. The place of an aftercomer is determined by dealing a card between every two players. The aftercomer sits where the lowest card was dealt. *Incorrect Packs.*—16. The deal in which an imperfection of the pack is discovered is void. All preceding deals stand good. (H. J.)

**POKROVSKAYA SLOBODA**, or **POKROVSK**, also **KASAKSTADT**, a village of the district of Novo-uzen, in the government of Samara, Russia, on the left bank of the Volga, almost opposite Saratoff. In the 18th century it was a small cluster of clay huts occupied by a number of runaway serfs who had gathered round the storehouses erected by the crown for salt brought from Lake Elton; but, a body of free settlers having been enticed to the spot in 1747 by large grants of grazing ground, the village rapidly increased, its inhabitants, who numbered 12,776 in 1859, now exceeding 20,000. They support themselves by cattle breeding and agriculture; and the Pokrovskaya landing place is one of the most important on the Volga, —the exports, mostly of wheat, reaching 99,850 cwts. in 1880.

**POLA**, the principal naval harbour and arsenal of the Austrian-Hungarian monarchy, is picturesquely situated at the south extremity of the peninsula of Istria, 55 miles to the south of Trieste. Its safe and commodious harbour is almost completely landlocked, and there is also a good roadstead between its mouth and the Brionian Islands. The harbour is divided into two basins by a chain of three small islands, and the inner basin is subdivided into the

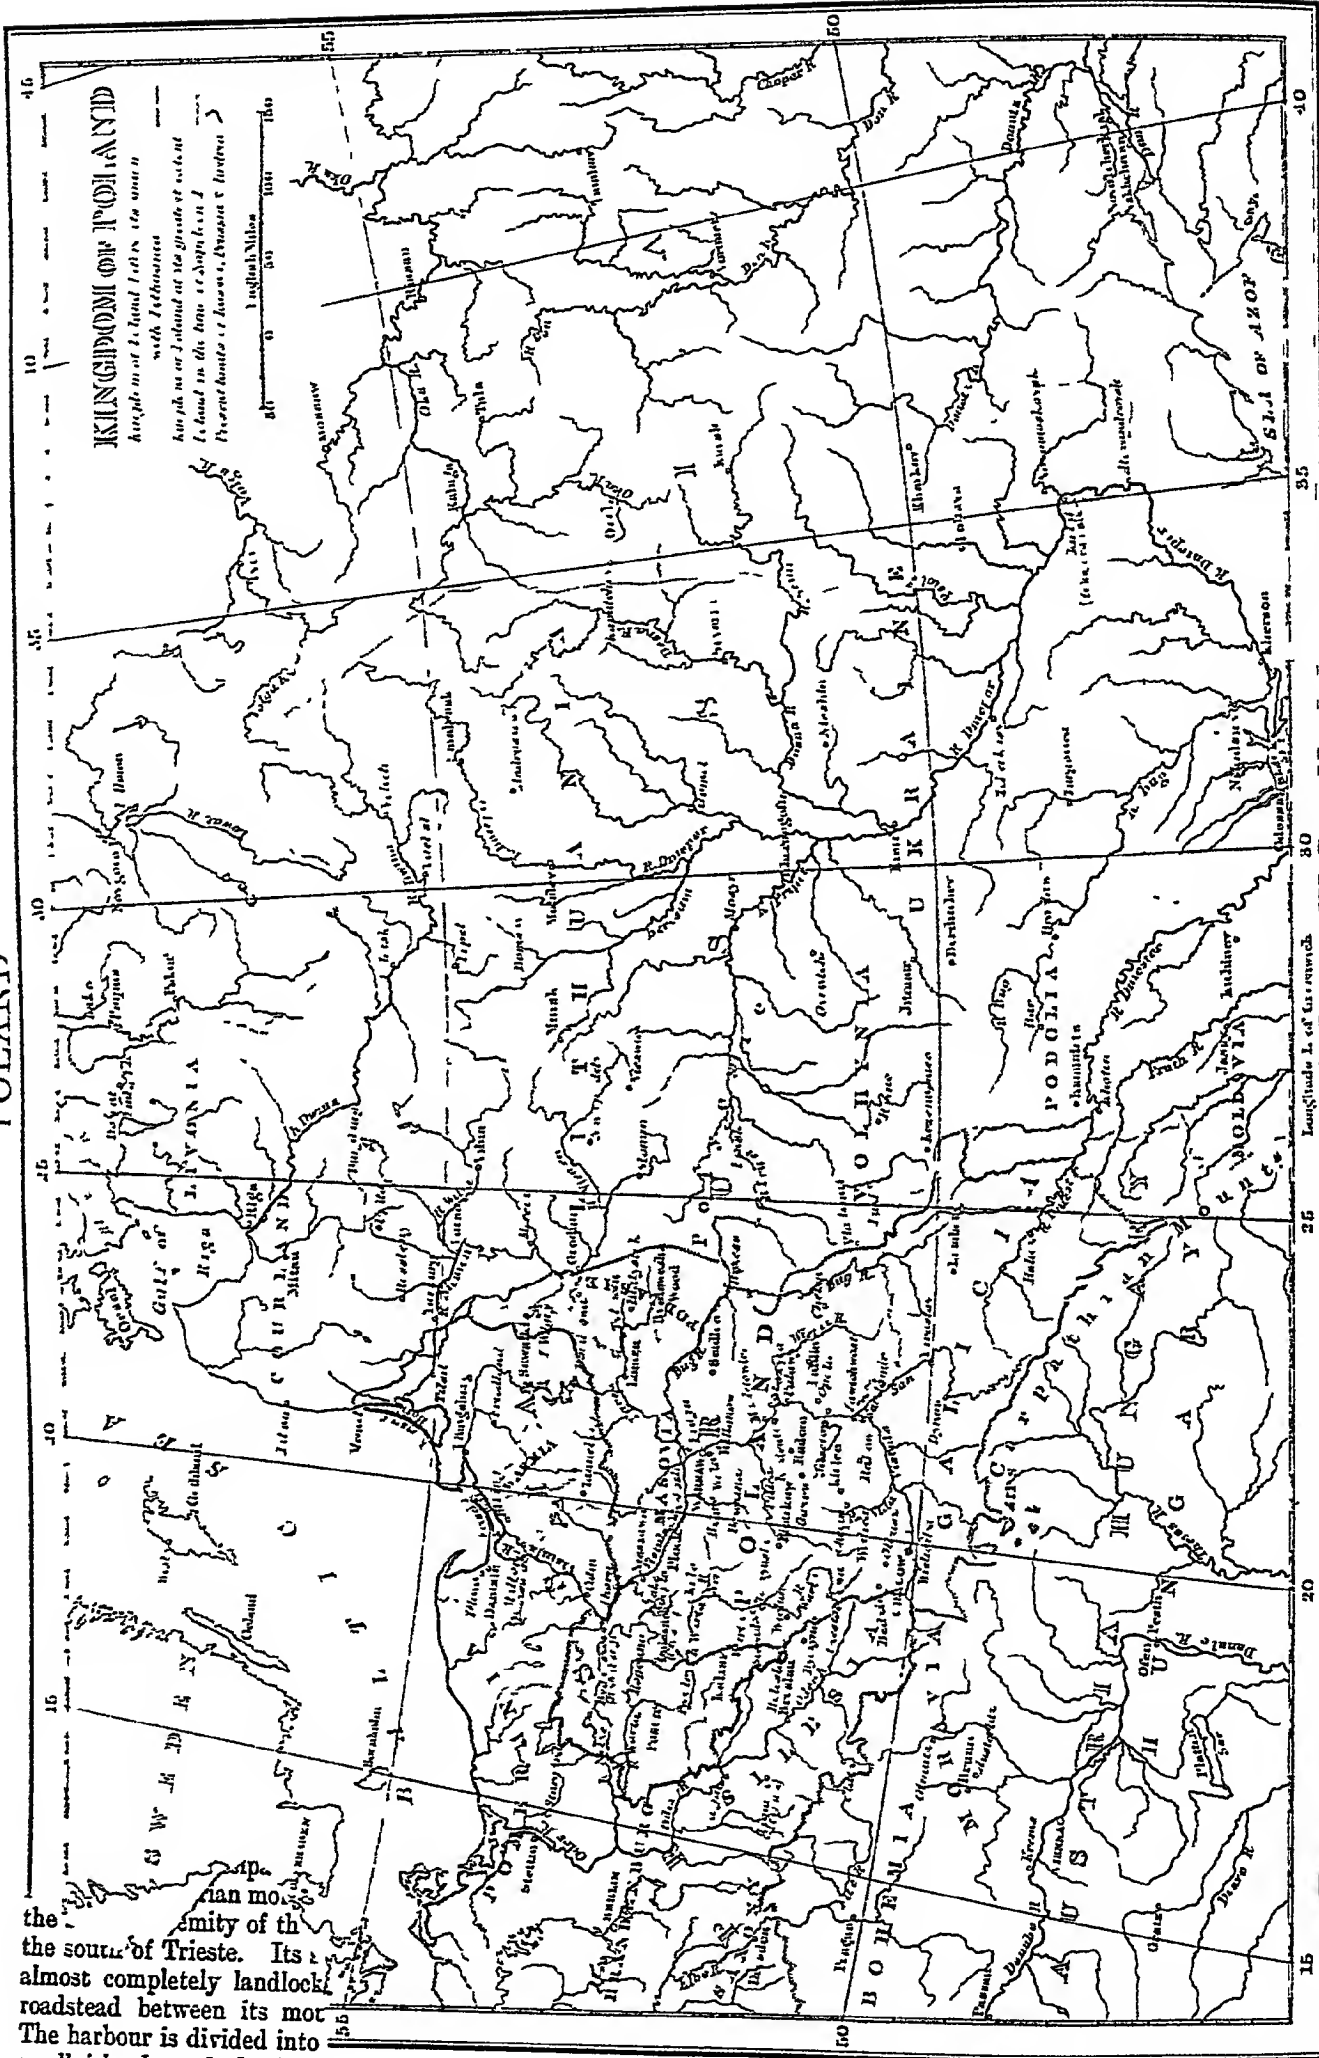

naval and the commercial harbour by the Scoglio Olivi, a larger island connected with the mainland by an aqueduct. The hills enclosing the harbour are defended by forts and batteries. The town proper lies opposite the Scoglio Olivi, round the base of a hill formerly crowned by the Roman capitol and now by a castle of the 17th century. Besides the castle the chief mediæval and modern buildings are the cathedral (15th century), the Franciscan convent (13th century), the Government and municipal offices, the huge infantry barracks, and the theatre. To the southwest, along the coast, extends the marine arsenal, a vast and well-planned establishment employing about 2000 workmen and possessing all the requisites for the equipment of a large fleet. It contains an interesting naval museum, and is supplemented by the docks and wharfs of the Scoglio Olivi. The artillery laboratory and the powder magazine are on the north bank of the harbour. Behind the arsenal lies the suburb of San Policarpo, almost exclusively occupied by the naval population and containing large naval barracks and hospitals. In the middle of it is a pleasant park, with a handsome monument to the emperor Maximilian of Mexico, who had been a rear-admiral in the Austrian navy. To the north, between San Policarpo and the town proper, rises the Monte Zarro, surmounted by an observatory and a statue of Admiral Tegetthoff. Pola has no manufactures outside of its naval stores, but its shipping trade is now considerable, the exports consisting of fish, timber, and quartz sand used in making Venetian glass, and the imports of manufactured and colonial wares. The population has increased from 600 at the close of last century and 5000 in 1857 to 25,175 in 1880, including a garrison of 5000 men. To many people, however, the chief interest of Pola centres in its fine Roman remains. The most extensive of these is the amphitheatre, which is 400 feet long and 320 feet wide, and could accommodate 20,000 spectators. It is remarkable as the only Roman amphitheatre of which the outer walls have been preserved intact; the interior, however, is now completely bare, — though the arrangements for the naumachiae, or naval contests, can still be traced. The oldest Roman relic is the fine triumphal arch of the Sergii, erected soon after the battle of Actium; and of not much later date is the elegant and well-preserved temple of Augustus and Roma. Among the other antiquities are three of the old town-gates and a fragment of a temple of Diana.

The foundation of Pola is usually carried back to the mythic period, and ascribed to the Colchian pursuers of Jason and the Argonauts. In all probability it was a Thracian colony, but its verifiable history begins with its capture by the Romans in 178 B.C. It was destroyed by Augustus on account of its espousal of the cause of Pompey, but was rebuilt on the intercession of his daughter Julia, and received (according to Pliny) the name of Pietas Julia. It seems to have attained its greatest prosperity about the time of the emperor Septimius Severus (193–211 A.D.), when it was an important war harbour and contained 35,000 to 50,000 inhabitants. At a later period Pola became the capital of the margraves of Istria, and was more than once captured and plundered by the Venetians, who finally made themselves masters of the peninsula. In 1379 the Genoese, after defeating the Venetians in a great naval battle off the coast, took and destroyed Pola, which disappears from history for the next four hundred and fifty years. It remained under Venetian supremacy down to 1797, and has been permanently united with Austria since 1815. In 1848 a new era began for Pola in its being selected as the principal naval harbour of Austria, and since then its progress has been constant.

## POLAND

**Plate I.** **P**OLAND (the Polish *Polska*, German *Polen*, French *Pologne*) was till towards the end of the 18th century a large and powerful kingdom, extending, with Lithuania, which was incorporated with it, over the basins of the Warta, Vistula, Dwina, Dnieper, and upper Dniester, and having under its dominion, besides the Poles proper and the Baltic Slavs, the Lithuanians, the White Russians, and the Little Russians or Ruthenians.

If Schafarik is correct in seeing the name of the Poles in the *Bulanes* of the geographer Ptolemy, we should have this Slavonic people mentioned as early as the 2d century after Christ.<sup>1</sup> There can be no doubt about the derivation of the name; the country is one vast plain, and thus the Poles come to mean dwellers of the plain or field (*polē*). Jordanes has no distinct name for them, although he speaks of Slavs inhabiting the banks of the Vistula. About the 6th or 7th century we find a people called Lekhs settled near that river, and this appears to be the oldest name which we can positively assign to the Poles. These Lekhs are considered by Szajnoch and some of the modern School of historians to have been a Norse tribe who in the 6th century ruled over the Slavonic peoples from the Baltic to the Carpathians. And, if this were the case, the origin of the Polish kingdom would be traced to the same source as the Russian empire. No satisfactory etymology has been given as yet of the word Lekh or Lech; we cannot accept Schafarik's attempt to connect it with *slachta*, nobility, as that word is in all probability derived from the German *geschlecht*. From the form of the word *Lech*, Russian *Liakh*, we can see that the vowel represents a suppressed nasal, and this is further proved by the change which it undergoes in the neighbouring languages; thus in Lithuanian we get *Leukas* and in Magyar *Lengyel*. The chronicle of Thomas, archdeacon of Spalato, calls them *Lingones* (Bielowski, *Mon. Hist. Pol.*), the Polish chronicles of Mierzwa and of Vincent Kadlubek *Lenchitæ*, *Linchitæ*. The loss of the nasal in the modern Polish form is curious, and contrary to the analogy of the language; it is supposed to have disappeared under the influence of Russian pronunciation. In the 13th century Kadlubek invented the imaginary *heros eponymus* Lekh, supposed to have been the father of the Poles, and two brothers were found for him, Czech and Rus.<sup>2</sup> A great similarity has been noticed between these early heroes and others among the Czechs. Thus we may compare Cracus and Krok, Piast and Přemysl. Many of the legendary tales greatly resemble Scandinavian sagas, as indeed much of the early Russian history does which is contained in the chronicle of Nestor. Gradually the name Lekh was superseded by Poliani or Polaki. Nestor, the old Russian chronicler, or at least the work which goes under his name, knows both appellations and distinguishes between *Poliane Liakhore* on the Vistula and *Poliane Rousore* on the Dnieper. When we first become acquainted with the Poles we find them like the other Slavonic peoples living in a kind of democratic communism, to which we need not assign the patriarchal simplicity and happiness in which some of their chroniclers, e.g., Długosz, would make us believe. All the early period of Polish history is mixed up with fables. Their first writers Gallus, Kadlubek, Długosz, Kromer, and others, who were ecclesiastics and used the Latin

language as their literary medium and handled it with considerable dexterity, have treated these stories as genuine history,—just as Holinshed, Milton, Sir Richard Baker, and others did the Arthurian legends. The careful criticism, however, of modern times has relegated them to their proper place, and Lelewel has classified all the period of Polish history from the earliest times to the reign of Mieczysław I. as belonging to the era of myths. We are hardly likely to believe in the existence of a Duke Lech or a beautiful Princess Wanda, who flourished in the 8th century, or in Cracus, said to have been the founder of Cracow. All these are obviously only generic and national names individualized. Many of the quaint and striking stories of these princes have done duty in all the legendary history of Europe. It cannot be doubted that poems corresponding to the Russian *byliny* are imbedded in the writings of these early chroniclers. The good peasant Piast, from whom was derived the celebrated line of kings, reminds us of the Mikoula Selianinovich of the Russians and the Přemysl of the Czechs. Kromer has tricked out the legend of his call to the throne in all the graces of his elegant Latinity.

Bielowski, the editor of the *Monumenta Poloniz* Views of Historica, in his *Wstęp Krytyczny do Dziejów Polski*<sup>3</sup> Bielowski ("Critical Introduction to Polish History") endeavoured to prove that the original Poles dwelt on the banks of the Danube, from which they were driven by the Romans. He also attempts to trace them in the 2d and 3d centuries after Christ. According to the whimsical theory of this author—a man to whom Slavonic history in other respects owes so much—the original habitation of the Poles was by the Lake of Ochrida. The Lęchites (Lyncestæ) in the 3d century before Christ were driven by the Celts beyond the Danube, and there the kingdom of Dacia was founded. King Boirebista is Leszek II., Decebalus is Semowit, &c. Lelewel and Bielowski seem to have identified all the Thracian peoples with the Slavs.

All that we are told of the early Slavs shows them to have been a quiet agricultural people. We find them at first living in village communities with a tribal government. Nestor says, "The Poliani lived in separate groups, and each governed his family." Gradually a class of serfs sprung up, whose origin cannot be clearly traced. Röpell in his history supposes that they were the descendants of rival tribes who had been conquered. At all events we soon find the following divisions of society among the Poles:—(1) the nobility, *szlachta*, who throughout Polish history constitute the nation properly so-called; (2) a superior class of peasants who were personally free, but bound to perform certain services (these are always called in the old Polish documents *emetones*, or *kmetones*, Polish *kmięci*); and (3) the peasants strictly so called, who were the property of their masters and had no rights. We shall see how there was gradually formed in Poland a proud military aristocracy, which circumscribed the power of the king by the *pacta conventa*, so that he became a mere puppet in their hands. The nobles had absolute power over their serfs, as each separate palatinate had its tribunals. In course of time the *kmięci* became mere bondsmen. The miserable condition of the latter is seen in such books as Connor's *Letters on Poland*, published at the conclusion of the 17th century. Connor, who was physician to John Sobieski, had good opportunities for

<sup>1</sup> There is another reading, *Sulanēs* or *Sulonēs*; but the former is preferred by the best editors.

<sup>2</sup> For a further discussion of this subject, see the indexes to M. Leger's *Nestor* (p. 328), and especially the *Archiv für Slavische Philologie* (vol. iii., *Ueber die Namen für Polen und Lechen*, by Prof. Nöhring, and vol. iv., *Polen, Ljachen, Wenden*, by Prof. Perwolf).

<sup>3</sup> The following directions for pronunciation may be useful:—*c*=*ts*; *cz*=*ch*; *sz*=*sh*; *ż*=*zh* (the French *j*, as in *jour*); *ł* has a thick sound which can only be acquired by ear. In nearly every word the accent is on the penult.

forming an opinion. Thus the trade of the country fell wholly into the hands of foreigners and Jews.

Mieczysław.

With the reign of Mieczysław I. (962-992) we begin to have something firmer in our grasp. He became a suitor for the hand of Dąbrowka, the daughter of the king of Bohemia. Being a Christian she refused to give her hand to a pagan, and Mieczysław consented to be baptized in 965. He had been previously conquered by the Germans, who seem to have enforced conversion from all whom they brought into subjection. After this he proceeded to extirpate the worship of idols in as autocratic a manner as Vladimir had employed, when at Kieff Peroun, the god of war, was thrown from his pedestal and ignominiously cast into the Dnieper. In 980 an edict was issued that every Pole who had not already submitted to baptism should immediately undergo it. No opposition was offered to this strange decree, which from its easy adoption would seem to have left but little impression upon the neophytes, and probably the chroniclers have some reason for their assertion that Mieczysław himself subsequently relapsed into gross sins. This complete conversion of the nation appears to have been aided by the labours of St Adalbert, bishop of Prague. Such traces as remained of the early Orthodox creed which had been introduced from Moravia were effaced, although they remained for some time in the sister kingdom of Bohemia, and we find a monastery established by the emperor Charles IV. for Greek monks at Prague. Mieczysław acknowledged himself to be the feudatory of Otho of Germany; he also resisted the encroachments of Vladimir of Russia, for already the feud between the two nations was commencing. He died in 992 universally regretted, as we are told, and

Bolesław the Great.

was succeeded by his son Bolesław, surnamed the Great. During his reign Otho III. of Germany paid him a visit, and the Polish prince received him with such magnificence that the emperor elevated his duchy into a kingdom, probably intending that it should always remain a fief of the empire. Długosz and Kromer vie with each other in describing the splendour of this meeting; they are, however, far outdone by their predecessor Gallus, who speaks of magnificent military manœuvres prepared by Bolesław to delight his guest, and of the gorgeous array of the lords and court ladies; "for gold," he adds, "was at this time held as common as silver and silver as cheap as straw." Finally, Otho hailed Bolesław as king, and himself put the diadem upon his head. At his departure he presented the Polish king with the lance of St Maurice, still to be seen, as Kromer tells us, in the cathedral of Cracow; and Bolesław in turn offered as a gift the arm of St Adalbert, the patron saint of Poland. Lelevel treats the whole story of this coronation as a myth, because, as he observes, at that time kings were always crowned by bishops. Bolesław afterwards defeated the Russian prince, and spent the latter part of his reign in administering justice throughout his kingdom. By the commencement of the 11th century he had absorbed nearly all the western Slavonic states, including Bohemia. He enjoyed among his subjects the epithet of *Chrobry*, or brave. The Germans, however, in derision of his corpulence, which he endeavoured to lessen by hunting, called him *Trinkbier*. To him is due the foundation of the archbishopric of Gniezno (*Gnesen*), the chief see in Poland.

Towards the end of his life he sought to aggrandize himself at the expense of Russia. He had previously, in 1013 according to Thietmar, given his daughter in marriage to Sviatopolk, the nephew of Vladimir. His expedition against Kieff is alluded to by Nestor, but narrated more in detail by Thietmar and Martin Gallus. According to the latter he entered Kieff with the Polovtzi as his auxiliaries, and struck the golden gate with his

sword. He was succeeded by Mieczysław his son, who abandoned himself to pleasure and left the kingdom in a disordered state. He is said to have first divided Poland into palatinates, a term which will be explained shortly. On his death an interregnum ensued and his queen Ryxa, niece of Otho of Germany, held the regency. Owing, however, to the continual feuds between the Slavs and Germans, she was driven out of the kingdom and betook herself to Saxony, whither her son soon followed her. During their absence Poland presented a spectacle of anarchy, the commencement of the long series of miseries of this unhappy country. The serfs are said to have risen everywhere and massacred their lords, and even the priests were not spared. Moreover, two foreign wars, with Bohemia on the one hand and Russia on the other, increased their miseries. The pious Kromer chiefly laments the sacred relics carried off by the ferocious Bohemians which were never restored. To heal the universal wounds it was resolved to send for Kazimiérz (Casimir), the son of Mieczysław and Ryxa. But it required some time to find him, for he was hidden in Germany, although the story of his having become a monk in the abbey of Cluny in Burgundy, has been shown by Röpell to be groundless. We shall see afterwards that a Polish king did actually seek in a cloister rest from the turbulence of his subjects. Kazimiérz married Maria the sister of Yaroslav, the prince of Kieff, who was willing to abjure the Greek faith, and embracing the Latin took the name of Dobrogniewa. By this marriage he became the brother-in-law of Henry I. of France, who had married another sister. This king induced several monks to come from Cluny, and founded two monasteries for them, one near Cracow and the other in Silesia, at this time forming part of the kingdom of Poland. From the earliest period we find the country inundated with foreign ecclesiastics; and to this cause we may probably trace the long use among the Poles of the Latin language. Kazimiérz was succeeded by a second Bolesław (1058-1101), of whom many curious stories are told. In an expedition against Iziaslav, the prince of Kieff, he took that city and remained in it some time with his troops. The stay of Bolesław and his soldiers at Kieff is said to have been attended with the same deleterious effects as befell Hannibal and the Carthaginians at Capua; and the conduct of the Polish ladies during the absence of their lords, unless the chroniclers belie them, cannot be held up as an example to wives. The whole story, however, has a very mythical air.

The most remarkable event, however, of the reign of Bolesław was the murder of St Stanisław. In this respect he emulated Henry II. of England; he dared to come into collision with the ecclesiastical power, but he did not suggest the assassination of so prominent a person to others; he accomplished the deed with his own hand. His excesses had long drawn upon him the censure of Stanisław, who concluded by putting all the churches of Cracow under an interdict. Upon this the king vowed vengeance on his denunciator. The Polish chroniclers tell us that, on hearing that the saint was to celebrate mass in a chapel, he took with him a few determined followers and hurried to the place. He, however, forbore to break in upon the scene till the service was concluded. This being over, he ordered some of his attendants to enter and slay the prelate. They were restrained, however, by a miracle, for, endeavouring to strike Stanisław to the earth, they all suddenly fell backward. Again and again Bolesław urged them on, and the miracle was repeated a third time, until the king rushed in and with one blow clove the skull of the ecclesiastic. Kromer tells us that immediately after the murder the king and his impious satellites slashed the body, separated it into many pieces, and cast

it to be devoured by dogs and birds of prey. It was, however, guarded by eagles who kept off the assailants; and, some monks collecting the remains, they all became mysteriously reunited and were afterwards honourably interred at Cracow. Such a crime was not likely to go unpunished in those days. Gregory VII. (Hildebrand) placed the whole kingdom under an interdict. Bolesław, regarded with hatred by all his subjects, fled into Hungary, but of his end we have no certain information. After the disappearance of Bolesław, who had taken his son with him, the state remained nearly a year without a sovereign. Finally, being afraid of a Russian or Hungarian invasion, the Poles called to the throne Władysław (Ladislaus), the brother of Bolesław. Anxious to remove the interdict, he at once despatched ambassadors to the pope; but, although the churches were allowed to be reopened, so great was the authority of the occupant of the chair of St Peter, who refused again to ratify the title of king, that for two hundred years from this time no Polish ruler could legitimately assume such a dignity, but was obliged to consent to the humbler appellation of duke. Władysław, who was engaged in constant wars with the Russians and the heathen inhabitants of Prussia, died in 1202 at Płock,—as was suspected, of poison. The power of Poland was diminished in his reign, as many provinces were occupied by the Russians. He was succeeded by his son, Bolesław III., to whom the Poles have affixed the surname of Krzywousty, or the Wry-mouthed. Kromer tells us, "Fuit autem Boleslaus hic, habitudine corporis satis firma, vegeta, et laborum patiente, colore fusco, statura mediocri, os ei carbunculus morbus ab ineunte adolescentia distorserat, atque inde Criuousti eognomentum habuit." He married Sbislava, the daughter of Sviatopolk, the prince of Kieff, and was successful in many wars, till, having eventually been defeated by the Hungarians on the banks of the Dniester, he is said to have died of grief. He seems to have been a redoubtable warrior, and to have distinguished himself in some very hard fighting. His expeditions against the Pomeranians were characterized by much cruelty, for we are told that Gniewomir, one of their chiefs, was beaten to death in the presence of the Polish army. Besides his attack upon the Pomeranians we learn from Gallus that he also marched against the Prussians, whom he utterly defeated, returning with a large spoil of cattle and other booty. His most important war, however, was with the German emperor Henry V., the husband of Matilda, the daughter of our Henry I. He had probably become jealous of the rising power of Bolesław, for the Germans at that time affected to regard Poland as a fief of the empire. The only event of much interest in this war is the gallant defence of Glogau, where the imperialists were driven off, in spite of their furious onslaught, and were ultimately routed near Breslau. The emperor fled precipitately, and the Poles gave little or no quarter. The field, says Kromer, where the battle took place was full of corpses, and exhibited a sorry and lamentable spectacle. The bodies of the Poles were carefully sought out and interred, but the Germans were unburied and lay as food for dogs and birds. In consequence of this the number of dogs who frequented the spot was so great that the road was rendered difficult to travellers. The place was called the Field of the Dog both by the Poles and Germans, a name which has obtained till the present day. Kromer, however, tells us that some of the German historians claimed the victory for their nation. Whatever the result may have been, peace was soon afterwards made between the emperor and the duke, a peace which was further consolidated by the marriage of Bolesław and his son Władysław to members of the imperial family. Before his death the Polish duke, following the same fatal

course which in Russia paved the way for its subjugation by the Mongols, parcelled out his territories to his sons Władysław, Bolesław, Mieczysław, and Henry. There remained a fifth and youngest son, at that time of tender age, Kazimierz. The duke being asked why he had left him portionless is said to have declared that the four-wheeled chariot must have a driver, thus, as it were, prophesying the future pre-eminence of this child. The prediction, which looks very much like a prophecy after the event, reminds us of William the Conqueror distributing his kingdom to his sons. The quarrels of these princes are very tedious. Władysław was ultimately driven out and Bolesław became supreme. His subjects gave him the nickname of Kędzierzawy, or the curly. He was drawn into a contest with the German emperor Frederiek Barbarossa, who invaded Poland in the year 1158. It would have been impossible for Bolesław to meet so formidable a foe in the field; he, however, succeeded in forcing him to make peace by continually harassing his army, and laying waste the territory before it. Frederiek again attempted to convert Poland into a fief of the German empire, but failed. Bolesław signed a peace by which he consented to give Silesia to his brother Władysław, and the Poles were to furnish three hundred spearmen to assist the emperor Frederiek against Milan. An expedition which he undertook against the Prussians in 1167 was unsuccessful; in consequence, as Kromer assures us, of treachery, the Poles became entangled in the marshes of the country and were cut to pieces. On his death Bolesław was succeeded by his brother Mieczysław, who was so unpopular that he was expelled from the country in 1177. The crown, therefore, according to the prophecy, devolved upon Kazimierz, the youngest son of Bolesław Krzywousty. During his reign many judicious laws were passed in Poland; among other improvements he abolished the evil custom of purveyance. His reign was tranquil, and by summoning a council of the bishops and nobles at Łęczyca he may be said to have instituted the Polish senate, at all events to have laid the foundations of it. At this time the third crusade was preached in Poland, and the order of the Cistercians was introduced into the country. We shall pass rapidly over the reigns of Leszek V. (the White), Władysław III., and another Bolesław. Conrad, duke of Masovia and brother of Leszek, introduced the order of Teutonic knights into the Polish territories on the Baltic, from whom the Prussian monarchy, one of the great enemies of the republic, was afterwards to develop itself. In the reign of Bolesław V. (1227-1279) the Mongols made an incursion into Poland, but were subsequently diverted into Hungary, having gained a victory at Lignica (Liegnitz) in Silesia in 1241. They carried off great quantities of booty. It is said that on this occasion nine sacks were filled with the ears of the slain. During their stay Bolesław, like Ivan the Terrible at a later period, remained cloistered in a monastery. Lelewel dwells pathetically upon the many evils suffered by Poland during the long reign of this prince, and says he was an unjust judge, a soldier who had aversion to fighting, and a sovereign who neglected the government. At this time also commenced the introduction of Germans into the country in such numbers as to threaten to denationalize it. The trade was almost entirely in their hands, and instead of being governed by Polish laws they enjoyed the benefit of the *Jus Magdeburgicum*. The wide influence of these foreigners is shown by the many words of German origin to be found in the Polish language.

An unfortunate and uninteresting prince, Leszek the Black, succeeded, but the dignity of the house of Piast was fully restored when Przemysław, without condescending to solicit the title of sovereign from the hands of the pope,

received the crown from his nobles and clergy at Gniezno (Gnesen). Thus did Poland again become a kingdom. This unfortunate prince, however, was afterwards murdered by the margrave of Brandenburg at Rogozno (1295). The reign of Waclaw (Wenceslaus) (1300-5) was not of great importance. He united the crowns of Poland and Bohemia, but soon became unpopular on account of his preference of his Bohemian subjects. Shortly after his election he left the country, and, confiding the control of Poland to the Bohemian garrisons, retreated with his wife to Prague, having been invited to take the crown of Hungary, which he soon abandoned to his son. His death in the year 1305 was accompanied by suspicious circumstances which rendered it probable that it had been brought about by poison. With him expired the race of the holy peasant Přemysl, which had ruled Bohemia according to the ancient chronicles for nearly six hundred years. The relations of the latter country to the German empire were now to become much closer. Władysław Lokietek, who succeeded Waclaw, was constantly engaged in wars with the Teutonic knights. In three expeditions against them he allowed his troops to commit great excesses. A full account of them may be found in Kromer, who has given us a florid speech said to have been uttered by Władysław before one of the battles. Several heretics at this time made their appearance in Poland, advocating among other things communistic doctrines. They were severely repressed, and from this time dates the establishment of the Inquisition in the country which lasted till the days of Sigismund I. About 1312 Cracow appears to have been made the capital of the kingdom, and continued so till the reign of Sigismund III.

Casimir  
III.

Władysław was succeeded by his son Kazimierz (Casimir) III., justly surnamed the Great, whose reign was a golden period for Poland. The material prosperity of the country increased very much at this time. Commerce was active; the Russians supplied the inhabitants with furs; the southern parts of Europe sent wines, carpets, silks, cotton, &c. The principal towns of Poland, Dantzic and Cracow, to assist the development of their commerce, joined the Hanseatic league. The towns on the Vistula now began to increase in number and importance, and we first hear of Warsaw, which, however, was not made the capital of the kingdom till the reign of Sigismund III. In 1364 Kazimierz laid the foundation of the university of Cracow, but it was reserved for Queen Jadwiga to carry out his plans. One of the most important events of his reign was the passing of the statute of Wislica (1347). In this legal document the palatines and castellans are mentioned, and the authority possessed by them is carefully defined. It may be well to enumerate here some of the chief functionaries of the republic. The duty of a palatine was to lead the troops of his palatinate on any military expedition, and to preside in the little diets or assemblies of the nobility of his province. Immediately after the palatines came the castellans, who, like the former, were all senators. They were lieutenants of the palatines in time of war, leading the nobility of their jurisdiction into the field, under the command of the palatines. Both the palatines and castellans held judicial tribunals in their respective provinces. The *nuntii* (*posły*) were the deputies returned by the various districts of the palatinates. There were sixteen ecclesiastical senators, including the primate (the archbishop of Gniezno) and the archbishop of Lemberg. They all sat in one house. The *starostas*, employed in collecting the revenue and other functions, had no seat in the house. There are many things in the statute of Wislica favourable to the peasant; thus the power of life and death over him, which his master had previously enjoyed, was abolished. The peasant was not *glebe ascriptus*, and if ill-

treated by one lord could move to the estate of another. The inhabitants of the towns, foreign and chiefly German artisans were governed by the *Jus Magdeburgicum*; but appeals to Magdeburg itself were prohibited; for this purpose a Teutonic tribunal was established at Cracow, consisting of a judge properly acquainted with foreign law, and of seven citizens nominated by the starosta. Kromer, in his *Polonia*, says, "*Legum scriptarum nullus fuit usus apud Polonos vetustioribus temporibus; nec ullæ extant antiquiores iis quas Cazimirus magnus rex condidit.*" A national diet was now being formed. It consisted of the upper clergy and the nobles, but the inferior clergy and the citizens seem sometimes to have been admitted. Gradually questions of peace and war were introduced and even the election of kings, the principle of departing from the hereditary line being admitted—a concession afterwards attended with great evils to Poland. The improvements of Kazimierz were not confined to law-making; he fortified the chief towns of his kingdom, and built many of their most handsome edifices. He also introduced many artisans from Germany. By his marriage with his first wife Anna Aldona of Lithuania, he had only a daughter. He therefore convoked a diet at Cracow on the 8th May 1339, in which he proposed as his successor his nephew Louis of Hungary, the son of his sister. This was to concede to the diet a very important privilege, as the throne became virtually elective. The nobles were not slow in availing themselves of the concession which had been made to them. Before they allowed Louis to succeed they exacted some very important terms from him which became the foundation of the celebrated *pacta conventa*. The year after the appointment of a successor his wife died. According to Kromer she was passionately fond of music, and took musicians with her wherever she travelled. The wars of Kazimierz against the hereditary enemies of the country, the Russians, Lithuanians, and Mongols, were successful. His private life was stained with licentiousness, but his reign marks a distinct epoch in the political and legislative development of the country. With him the glory of Poland begins, and he is well worthy of the glowing eulogy of the national historian Dlugosz. We cannot wonder also that the Poles dwell with pleasure upon the splendour of the court of Kazimierz, but he certainly squandered the royal treasures too freely. We are told that at one time he entertained at Cracow the emperor of Germany and the kings of Denmark, Hungary, and Cyprus. His death was occasioned by a fall from his horse while hunting near Cracow on the 5th November 1370, and with him expired the line of the Piasts. Casimir was succeeded, Louis, as had been arranged, by Louis of Hungary, who held the crown for twelve years only, and of that period spent but a short time in the country. Louis showed too great a fondness for his own subjects; he had also the misfortune to be unacquainted with the Polish language. After his death his second daughter Jadwiga was elected queen, but Jadwiga she was to accept as husband any prince whom the diet might propose to her. Her election is declared by Kromer to have been due to the eloquence of one Jan Tęczyński (a member of a celebrated Polish family), whose speech, or an imaginary reproduction of it, is given at great length in very classical Latinity. Jadwiga is said to have been a woman of great beauty and worth. As a matter of state policy she was induced to marry Jagiello, the prince of Lithuania, a man of savage manners; but Lithuania was thus annexed to Poland, with which it remained joined ever afterwards,—a more complete federation having taken place at Lublin in the year 1569. Jagiello was a pagan, but he offered to renounce his creed and to introduce the Christian faith into his dominions; although not educated in that religion he was born of a Christian mother, and its

doctrines were not entirely strange to him. The principality of Lithuania at that time stretched from the Baltic to the Black Sea, and eastwards to within a short distance of Moscow. Its religion was Greek Church, and its official language White Russian. The Lithuanian tongue, so interesting to the philologist, seems never to have been anything more than a peasants' language, and no official documents whatever have come down to us in it. This was not the first marriage between the sovereigns of the two countries, as the first wife of Casimir the Great, Anna Aldona, had been a daughter of Gedymin, a Lithuanian prince. Originally Jadwiga felt a repugnance to the marriage with Jagiello on account of the coarse and repulsive manners of the barbarian, and also because she had previously plighted herself to the archduke William of Austria. The matter was referred to her mother Elizabeth of Hungary, who expressed herself favourable to the marriage. The archduke, however, did not abandon his hopes without a struggle; he made his appearance with a splendid retinue at Cracow, but eventually retired on finding that the prosecution of his suit would lead to no favourable result. The new candidate arrived at the metropolis after him, and Jadwiga accepted his proposals. In 1386 they were married, and from that year we may date the commencement of the dynasty of the Jagiellons in Poland, which lasted for nearly two centuries, terminating in 1572,—indeed, we may say nearly a century longer, omitting the short and brilliant period of Batory (1576-1586), for Sigismund III. was the son of Catherine daughter of Sigismund II., and Wladyslaw IV. and John Casimir were his sons; after the death of the latter the throne became entirely elective. The new sovereign was baptized by the name of Wladyslaw. Having been converted himself, he forced his subjects to be converted by the simple process which seems to have prevailed over all Slavonic countries. Wladyslaw is said to have assisted in these pious labours with persuasion as well as command, and by these means Lithuania, which had remained heathen longer than any other part of Europe, was finally Christianized. We are told, however, by travellers of heathen customs remaining long afterwards. Although owing so much to his consort, the king seems to have treated her with jealousy and suspicion. On his impugning her chastity, she insisted on being confronted with her calumniators. The investigation resulted in Jadwiga's triumphant acquittal; and we are told by Dlugosz that her accuser was compelled in the singular fashion of the country to prostrate himself under a table and declare that he had lied like a dog, and at the same time to imitate the barking of that animal. We are further informed that this punishment for defamation continued in force in Poland until the close of the 18th century. The nobles wrested several important privileges from Wladyslaw; and from this time we can trace step by step the rise of that fierce oligarchy which brought so much trouble upon the unfortunate kingdom. They secured for themselves exemption from all contributions when called to serve beyond the frontiers, and an allowance of five marks for every horseman; they also procured the exclusion of members of the royal family from all the higher offices of the state, reserving these for themselves. In the reign of Wladyslaw many expeditions were undertaken against those inhabitants of Lithuania who preferred to remain pagans. In 1410 also occurred the great battle of Grünwald near Tanneberg in Prussia, in which the Teutonic knights were completely defeated and Ulrich von Jungingen, the grand master, killed. Wladyslaw died in 1434, and was succeeded by his son of the same name. His queen Jadwiga had died in 1399; she appears to have been greatly beloved by the Poles, and was canonized after death,—miracles, it is said, being wrought at her

intercession. The consolidation of Lithuania with Poland was destined to be a much more tedious and protracted matter than its somewhat violent union. Great as may have been the grief of Wladyslaw at the death of Jadwiga, it did not prevent him from contracting three subsequent marriages,—the third wife being Sophia, a princess of Kieff.

The younger Wladyslaw was able soon after his accession to add (by election) both Bohemia and Hungary to his dominions. He then commenced an expedition against the Turks, who under their sultan Amurath II. were pressing the siege of Belgrade, having already annihilated the ill-starred Lazar and his army at the battle of Kossovo in 1389. At first Wladyslaw was everywhere successful, and had instilled such terror into the Turks that Amurath proposed a truce for ten years and offered to cede all his conquests except Bulgaria. The conditions, having been accepted, were ratified by mutual pledges; unfortunately Wladyslaw was induced by Cardinal Cesarini to recommence the war and violate his oaths. The sultan on hearing of this perjury at once prepared for battle at the head of a formidable army. The encounter took place at Varna, in the present principality of Bulgaria. After performing prodigies of valour, Wladyslaw was defeated and slain. Hardly a fifth part of the Polish army escaped from the battle, and of these many perished in the swamps of the Dobrudja. This melancholy engagement, which formed, as the Polish chroniclers tell us, the subject of so many lays—whereof it is a great pity that none have come down to us—is fully described by Kromer (p. 327-8), who adds many omens and pious reflexions. He dwells with delight upon the conspiracy of twelve noble captives, who would have murdered Amurath if their plot had not been revealed by a Bulgarian, whereupon they committed suicide: "In necem ejus conjurarunt, peregisentque facinus preclarum et omnibus seculis memorabile nisi in ipso articulo a Bulgaro, quem unum consilii socium adhibuerant, proditi essent." There is also another curious account in the *Memoirs of a Janissary*, an early Polish work which will be further described in the section devoted to literature. The memory of the unhappy young prince, who was only in his twenty-first year, was long cherished amongst his countrymen, although, as Kromer tells us, during his short reign he almost drained the treasury and was so busied with the Turkish war that he had but little time to attend to the wants of his Polish subjects. The votaries of Mohammed were now beginning to make themselves a great name in Europe, and were already marching triumphant over the ruins of the effete Eastern empire. The imperial city itself was soon to fall, and the crescent to be placed upon the domes of Saint Sophia.

After a brief interregnum Kazimierz, brother of the deceased king, was chosen to succeed him; he had previously been grand-duke of Lithuania. In this reign the Poles carried on successful wars with the Teutonic knights, which resulted in a peace, by which western Prussia, including Pomerania and the cities Dantzic, Thorn, and others, were to belong to Kazimierz, while eastern Prussia was left to the knights, who were, however, to hold it as a fief of the crown, and each subsequent grand master was to be the vassal (*holdownik*) of the Polish king and senate. Permanent encroachments were made, however, upon the dominions of the "Republic" (*Rzeczpospolita*) by Ivan III., who reannexed to the Russian crown Novgorod, which had been incorporated by the Lithuanians; he also appropriated a considerable portion of White Russia. The great Muscovite empire was now just becoming welded into a compact whole; with Ivan III. was to commence the era of consolidation, with Ivan IV. that of absolutism. In this reign the nobles first elected nuntii

or deputies (*posły*) to attend at the diet, when they themselves were unable to be present in person. They also passed some mischievous laws, aggravating the bondage of the miserable serfs. Previously it was possible for a peasant who had been ill-treated to fly from his lord; now it was enacted that he must be surrendered upon demand, and whoever harboured him incurred severe penalties. The researches of recent Polish historiographers have shown the importance of the reign of this monarch, who may be said to have consolidated the Polish kingdom; from his time the influence of the diet began. The statute of Nieszawa in 1454 has been called as important in Polish law as Magna Charta in English; it is the great charter of the rights and privileges of the Polish nobility.

John  
Albert,  
1492-  
1501.

Kazimierz was succeeded by his son John I., surnamed Albert (in Polish, Jan Olbracht), a feeble prince, most of whose wars were unsuccessful. He led an expedition against Stephen the hospodar of Wallachia, which resulted in a complete defeat. In this reign, at one of the diets (at Piotrkow in 1496,—for, as was the case with the parliaments anciently in England, they were held at various places), the nobles decreed that henceforth no burgher or peasant should aspire to any of the higher offices in the church; all such appointments they reserved to themselves. Thus they constituted their clergy a mere aristocratic caste, and imitated the prince-bishops and other spiritual potentates of the Germans. The peasantry were now obliged to bring all their cases before tribunals presided over by their own masters, where they were likely at best to get but a scant measure of justice. Finally, this memorable diet still further limited the power of the king by enacting that none of their sovereigns should in future declare war without their permission. Short as was the reign of John Albert, it saw him involved in many disputes with his nobility. An Italian refugee, Buonacorsi, who had been his tutor, gave him many suggestions with a view to limit the power of the nobility. About the same time, in 1497, some nobles were killed in an unfortunate expedition in Bukowina, and a report was spread that this disaster had been caused by the king himself through the bad counsels of Buonacorsi. In this reign also laws were passed in the diets further limiting the power of the burghers and the peasantry, who were now forbidden to possess any landed property. John Albert was succeeded by his brother Alexander, an utterly insignificant king; in his reign, however, we trace the first germ of the detestable *liberum veto*, which ruined Poland. In a diet held at Radom it was settled that the decision of the deputies was not to depend upon the majority, but must imply unanimity of suffrages. At a diet in 1652, as we shall afterwards see, it occurred for the first time that a single nuntius annulled by his *liberum veto* the decisions of the whole body present and broke up the assembly. By this absurd custom an element of confusion and disintegration was introduced into all the meetings; it was possible to hire a venal nuntius, for the majority of the Polish nobles seem to have had their price; and as soon as such a man appeared, however important the subjects to be debated might be, he could put an end to all further discussion. The lord high treasurer had the complete control of public finance; he was appointed by the king, but could not be removed. According to the strict letter of the constitution, he must give in his accounts to the diet, but he might easily evade doing so. As the diets only lasted six weeks he might bring them in too late, or if the scrutiny became somewhat tiresome he would probably be able to find a convenient nuntius who would veto the whole proceedings.<sup>1</sup> The story told by Connor of a certain Count Morsztyn, whom we shall find afterwards

mentioned among Polish authors, is certainly a very painful one. He says—"I may here give an account of a passage that happened when Count Morsztyn was great treasurer of Poland, who, having more regard to his own private interest than the public benefit, sent all the riches of the treasury into France, when, fearing that the diet would soon think fit to call him to account, he retired privately with all his effects out of the kingdom and went to settle in France, where he purchased the whole county of Château-Villain, which is worth above one hundred thousand livres a year." Such was the corrupt character of the Polish parliament. Other details are given of an equally painful description.<sup>2</sup> We are told that these meetings rarely happened without bloodshed. A serious fracas occurred among the turbulent nobles—who themselves, while dictating laws, embodied every principle of anarchy—when Sigismund III. was elected. Blood flowed in torrents, and the booths erected for the accommodation of the senators were burnt. At the election of King Michael balls from pistols flew about the tents of the senators, and nuntii were actually killed. Even worse scenes occurred at the election of Augustus II., as will be shown subsequently. In the reign of Alexander we find an instance where a few deputies from the towns were admitted, but their presence was only invited on rare occasions, reminding us how Ivan IV. now and then summoned the Russian citizens to his despotic *douma*. "He was of a middle stature," says Connor, "had a long visage and black hair, was very strong built but exceeding dull-witted, and consequently but a little talker. He exceeded all his brothers in generosity, and was wont to delight much in musicians and such trifling artists. Nevertheless, this his liberality was generally esteemed but prodigality, insomuch that some were so bold as to say that he died in time, or else both Poland and Lithuania might have been lavished away. To prevent the like pernicious generosity for the future, the diet made a law, calling it *Statutum Alexandrinum*, by which they revoked all this king's profuse gifts." In the reign of this sovereign the former statutes of Wislica, Warta, Nieszawa, and many others were confirmed and published in a single volume under the superintendence of the chancellor Sigismund Laski. The feeble Alexander was succeeded by his brother Sigismund (in Polish, Zygmunt), another son of Kazimierz. Sigismund was engaged in constant wars with Basil, the czar of Russia; his court was also filled with factions fomented by his wife Bona Sforza, the daughter of the duke of Milan, a woman thoroughly hated in her adopted country, on whom the Poles made the following epigram—

Si parcunt Parca, si luci lumine lucent,  
Si bellum bellum, tum bona Bona fuit.

When she left the country in the reign of her son Sigismund II., she carried large sums of money with her to Italy.

In this reign the order of Teutonic Knights embraced the doctrines of Luther; their dominions were already a fief of the Polish kingdom. Gradually this small principality was to absorb the Slavonic elements which surrounded it, and to rise triumphant over the ruins of Poland. The doctrines of the Reformation were now becoming widely spread over Europe, and the element of religious animosity was largely infused into this land of perpetual anarchy and tumults. Sigismund, however, was a man of remarkable ability, and under his rule the country flourished. He survived to the age of eighty-two, and his memory is still cherished with affection by the Poles. His broad heavy physiognomy may be seen accurately represented in the old editions of Kromer, who dwells

<sup>1</sup> See *Letters concerning the Present State of Poland*, 1773, p. 37.

<sup>2</sup> *Ibid.*, p. 27.

much upon his merits. In 1538 occurred the first *rokosz*, as it is termed in Polish, or rebellion of the nobility against the king. The affairs of Wallachia caused Sigismund to undertake a military expedition. Accordingly he appealed to the *respublica*, or commonwealth, as the Polish republic was called. One hundred and fifty thousand nobles assembled at Lemberg, but instead of marching to the war they laid their complaints before the king and refused to serve, and the old man was obliged to put them off with promises. The Lithuanians had not yet become reconciled to their union with Poland, even after so long a time, and one of their chief men, Gliniski, taking advantage of this feeling, attempted to restore its former independence to the country. Sigismund, however, succeeded in defeating Gliniski, who fled to Russia. He then persuaded the grand-duke to invade Lithuania, and assisted him in getting possession of Smolensk in 1514. Sigismund made a treaty with the grand-duke, but he did not succeed in getting back Smolensk. In 1526, by the death of the last of the dukes of Masow-sze (Masovia), this duchy was reunited to the crown of Poland. In 1533 Sigismund concluded a treaty with the Turks, then at the height of their power. This peace guaranteed to Poland the free navigation of the Black Sea, with the sovereignty of Moldavia, and prevented the irruption of the Mongols into Poland, where they were in the habit of committing great excesses, as the Little-Russian national ballads pathetically tell us. The reign of Sigismund was a period of great peace for Poland, and we may truly say that its glory at this time culminated. It seems a rule that the great men of a country are produced at periods of national prosperity, so we now find Copernicus flourishing, the one man of genius produced by Poland whose glory has resounded throughout the world. In 1529 Sigismund published his code of laws for Lithuania, which was issued in the White-Russian language, and forms one of the most important monuments of Polish law.

He was succeeded by his son Sigismund II. (1548-72), otherwise called Sigismund Augustus, but this prince was not elected till a very stormy debate had ensued as to whether he should repudiate his wife or not. He had married, as a widower (his first wife having been Elizabeth, daughter of Ferdinand of Austria), a fair widow of the house of Radziwill one of the most illustrious of the families of Lithuania. The nobles, however, who already treated their sovereign as a chief magistrate and nothing more, and had begun to control all his movements, required at the diet of Piotrkow that the marriage should be annulled, merely on the grounds that the country would gain more by his alliance with the daughter of a foreign potentate. But Sigismund, by sowing discord in the ranks of his opponents—proposing among other things to destroy pluralities in church and state—contrived to carry his point. His wife was crowned in 1550, but died within six months after, not without suspicions of having been poisoned by her mother-in-law. She is said to have made herself universally beloved during the short period in which the Poles had beheld her as queen. In three years' time Sigismund married a third wife, the sister of the first, and widow of Francis Gonzaga, duke of Mantua. During this reign the quarrels between Protestants and Romanists raged fiercely in Poland, and the latter were very severe in their persecutions. A priest was burnt to death for administering the sacrament in both kinds, and a lady suffered the same terrible fate for denying the real presence. Many of the nobles were infected with the new teaching, but Sigismund was disingenuous and inconsistent in his conduct. He is himself supposed to have been inclined to the doctrines of the Reformation; he certainly permitted Calvin to dedicate to him a commentary on

one of the epistles of Paul, and Luther an edition of his German Bible. Finally, realizing that the majority of his subjects were Catholics, he abandoned a faith to which he had perhaps given but a half-hearted adherence, and allowed the bishops to suppress with severity all promulgation of the new doctrines.

The religious question was keenly debated in a diet held at Wola near Warsaw the year after the death of Sigismund. It was resolved not to allow the sword to settle any religious differences. According to the language then used there was to be universal toleration. We shall soon see how little this was carried out. We find from it that the Polish peers were supposed to be masters of the spiritual as well as the material condition of their serfs, for it was expressly stated that their power over them was to be unlimited, "*tam in secularibus quam in spiritualibus*."

In his wars with Ivan the Terrible, in which the subject of quarrel was the Baltic provinces, Sigismund was not very fortunate; he was not able to prevent the Russians from acquiring the palatinate of Polotsk, nor could he subsequently hinder the Swedes from making themselves masters of Livonia. He died in 1572, leaving no issue by his three wives; and with him became extinct the race of the Jagiello, the second great family which had ruled over Poland. His reign was very favourable to the development of Polish literature. Then, too, the laws were first authoritatively promulgated in the native language, which was spoken at court, although Latin continued to be extensively employed. During the reign of Sigismund Augustus, Poland reached the height of outward prosperity. It included Lithuania and western Prussia, and by the addition of Masovia and Livonia extended its limits from the Baltic to the Black Sea, and almost from the Oder to the Don. The seeds of disintegration, however, had long been sown; since the marriage of Jadwiga with Wladyslaw Jagiello the crown of Poland had been more or less elective, although it continued in the same family. One important event which marked this reign must not be forgotten; in Diet of 1569 took place the celebrated diet of Lublin. By this a close union was effected between Poland and Lithuania, which up to this time had been ill united, and indeed there were continual jealousies breaking out during the existence of Poland as a nation—two great points being the difference of religion and language. Even the union of Lublin was not effected without considerable resistance. The following were its conditions:—Lithuania gives Podlasie to Poland; Livonia, under the title of duchy, belongs equally to the two states; Volhynia and the duchy of Kieff—that is to say, the Ukraine—are incorporated with Poland; the kingdom of Poland and the grand-duchy of Lithuania are to form a single indivisible republic, and are to have a single head, elected by their common votes; the senate is to be composed of nobles of both nationalities. Warsaw was fixed upon as the seat of the diet, since, being part of Masovia (Masowsze), it was, strictly speaking, neither Polish nor Lithuanian. It afterwards became the regular capital of the country in the reign of Sigismund III.; as we have seen, the first two capitals of Poland were Gniezno (Gnesen) and Craeow. Warsaw is of comparatively late origin. It is said to have been founded by Conrad, the duke of Masovia, in 1269. The old dukes of Masovia resided at Czersk near Warsaw, of which some of the ruins might be seen one hundred and fifty years ago (C. H. Erndtel, *Warsavia physice illustrata*, Dresden, 1730). The city is most advantageously situated, and with a better railway system and fewer fiscal restrictions would be one of the greatest emporiums in Europe. An interregnum now occurred on the failure of the line of the Jagiello, and the throne was publicly offered for competition. Four candidates appeared:—Ernest, arch-

Henry.

duke of Austria; Henry of Valois, duke of Anjou, brother of the French king; a Swedish prince; and finally Ivan the Terrible of Russia. The contest, however, really lay between the first two; the Swedish alliance was despised as likely to bring with it no solid advantage; the czar was hated both as coming from a race which had ever been hostile to Poland, and also on account of his detestable cruelties, which were well known throughout Europe. The political importance of France and the astute diplomacy of Montluc, the ambassador from that country, caused the decision to be given in favour of the French candidate. But, just as his name was brought forward as their probable king, the Poles, many of whom, we must remember, had embraced the Reformed doctrines, were startled by the news of the massacre of St Bartholomew (August 24, 1572). From the awkward dilemma in which he was placed by his complicity in this act, Henry endeavoured to escape by a falsehood,—impudently denying at first that anything of the sort had happened. Finding, however, but little credence given to his assertions, he attempted to explain away the affair and to lower the number of its victims, which he reduced to fifty, alleging that they had been really executed for a conspiracy. The Polish ambassadors duly made their appearance in Paris, showing their gay equipages, quaint and semi-Asiatic; their bows and arrows and shaven crowns with a single tuft of hair greatly amused the inquisitive French. Loose flowing robes, high boots, and a sword resembling a scimitar completed the *tout ensemble* of a Polish nobleman.<sup>1</sup>

Pacta conventa.

Readers of French history must be well acquainted with the character of this duke of Anjou, one of the most detestable of the house of Valois, who afterwards became king of France under the title of Henry III. The articles, some of which the Polish nobles required Henry to sign, called the *pacta conventa* so well illustrate the extraordinary influence of the aristocracy, and the shadow to which they had reduced the regal authority, that they are worth quoting *in extenso*. From this time every Polish king was compelled to accept them, together with the additions subsequently made.

(1) The king was to have no voice in the election of his successor; the appointment was to depend entirely upon the nobles.<sup>2</sup> (2) He was to keep rigidly the terms of the treaty made with the Dissidents, as the Polish Protestants were called. (3) No war was to be declared nor military expedition undertaken without the consent of the diet. (4) No taxes were to be imposed without the consent of the diet. (5) The king was not to appoint ambassadors to foreign courts. (6) If different opinions prevailed among the members of the diet, the king was to adopt only such as were in accordance with the laws or advantageous to the nation. (7) The sovereign must have a permanent council, consisting of five bishops, four palatines, and eight castellans, who were to be changed every year and elected by the diet. (8) A general diet was to be convoked every two years, or oftener, if there were any need. The assembling of these diets seems to have depended upon the will of the king. (9) The duration of each diet was not to exceed six weeks.<sup>3</sup> (10) None but a native could hold any dignity or benefice. (11) The king must neither marry nor divorce a wife without the consent of the diet.

Thus the regal shadow who was to sit upon the throne of Poland was able to interfere but little in questions either

<sup>1</sup> The Poles regarded the national dress with peculiar fondness, and Coxe tells us that they were somewhat indignant with their last king, Stanislaus (Stanislaw August Poniatowski, 1764-95), because he always appeared with flowing hair and adopted a French style of dress. They even meditated introducing a new clause into the *pacta conventa*, requiring that every king of Poland must wear the Polish dress.

<sup>2</sup> We shall find, however, this rule sometimes infringed, and instances occur in which the opinion of a sovereign affected the next nominee. Thus the malicious wife of Sobieski was able to exclude her son James from the succession, to which the national voice had almost called him.

<sup>3</sup> We shall afterwards see that this mischievous law was fruitful of evil consequences to the country, as frequently debates upon the most important questions would be brought to an end by the interference of one of the nuntii declaring that the legitimate six weeks had elapsed.

of peace or war. The latter, we have seen, he could not declare; and, as each of the palatines held nearly supreme power in his own territories, the king could interfere in little relating to the former. A vexatious control was exercised even over his private relations; his wife could not be of his own choosing, and, however odious she might become to him, she must remain attached as a state appendage till his nobles consented to release him. Not that Henry was likely to trouble himself with any scruples on the score of marriage. He arranged all those matters very easily. What was left for the Polish king was chiefly to eat and drink at the expense of his subjects, and to form a glittering addition to their costly and semi-barbarous pageants. Still his revenue was ample, and when he commanded the army in the field his power was unchecked; he had also the nomination to the highest ecclesiastical and military appointments.

Even before the severe terms of the *pacta conventa* had been presented to Henry, Montluc had agreed to all, but probably felt convinced that his sovereign would carry out no more of them than he could possibly help. He even promised that France should send a fleet into the Baltic, so that its dominion might be secured to the Poles, and that in the event of a war with Russia she should supply four thousand of her best troops, and herself pay their expenses; in all cases of war she was to aid Poland with money. Henry was to spend a large portion of the rents which he drew from his estates in France for the benefit of his adopted country; he was also to pay the crown debts, and to educate one hundred young Polish nobles either at Paris or Cracow. Probably no sovereign in the world ever signed such galling stipulations. Henry, however, had no intention of observing them, and had so little relish for his new kingdom that he did not set out till he had almost been driven from France by his brother, and the Polish nobles already talked of a new election. He proceeded on his way slowly, with all the dignity of a royal progress, but did not escape the gibes of the German princes through whose dominions he passed, for his connexion with the massacre of St Bartholomew. He was feasted at Heidelberg opposite a large picture which delineated the tragedy in all its horrors, and attendants were allotted him selected from French Huguenot refugees. He was crowned at Cracow in February 1574, but soon began to repent of his choice. The effeminate king relished but little the throne he had chosen among a warlike and turbulent people, where he seemed to enjoy but the shadow of sovereignty—a people also in every way inferior in civilization to the agreeable Parisians he had left behind. He felt himself a mere puppet in their hands, and, burying himself in the recesses of his palace, led a life of dissipation. But release was at hand in an unexpected way; he was destined to be king of Poland for five months only. By the death of his brother Charles IX. he became heir to the French crown. This delightful piece of news he attempted at first to conceal, and to escape before it could get noised abroad in Poland, principally to avoid the ambitious designs of his brother, the duke of Alençon; but unfortunately the report oozed out. He refused to follow the counsel of his advisers that he should convocate a general diet to see what measures should be taken. On the evening of the 18th July he gave a grand entertainment in honour of the sister of the late king Sigismund. The conviviality was great; and never had Henry assumed a more pleasing manner or seemed more genially to identify himself with his new subjects. At the usual hour, to all appearance, he retired to his apartment and the lights were extinguished; but already the king had flown. He was led by an attendant through secret passages to a chapel in the suburbs of the city, as some say—but accord-

ing to a more probable account to the royal stables, where a rendezvous had been appointed. Here horses had been prepared; and with a few chosen attendants he rode precipitately from his kingdom, reaching the frontiers of Silesia early on the following day. Great was the consternation in Cracow when it was known that he had fled, and hot the pursuit of the authorities. The probability of the king's flight, gathered perhaps from his ill-concealed uneasiness, had caused it to be suspected before it was known as an actual fact. The grand chamberlain, anxious to calm the universal excitement, returned to the palace to which by virtue of his office he had general access. At first he knocked at the king's door, but no answer was forthcoming; he then tried the chambers of the gentlemen-in-waiting; there equally he found a dead silence. Again, he returned to the king's bedroom, and, not being able to force the door, entered by the window—for even in matters of etiquette they seem in Poland to have treated their kings somewhat roughly. The candles were burning as usual in the room; the two pages were near the bed; the curtains of the bed were drawn, but there was no Henry to be found. The grand chamberlain, amazed, rushed in pursuit, attended by five hundred cavaliers. Probably such a ludicrous sight had never been seen before as a monarch flying from his kingdom and subjects without being driven out by them. Owing to his ignorance of the route the horsemen were soon on his track, and many of his companions, to save themselves, deserted him. One of them named Pibrac hid himself in a log, and was even obliged to make several dives to escape the infuriated peasants, who pelted him with stones, unconscious of what he had done, but satisfied, from his efforts at concealment, that he must be flying from justice. In vain did Henry cause the bridges to be broken down behind him; the Slavs on his track forded the rivers on horseback, and the king was at last overtaken on the very boundaries of the German empire. There Tęczyński, the grand chamberlain, and five horsemen came up with the fugitives and shouted after the king, "Serenissima Majestas, cur fugis?" Finding that he was quite safe, Henry admitted Tęczyński to an audience, who remonstrated with him on account of the manner in which he was leaving the kingdom, and recommended him to return and convoke a diet so that with the consent of his subjects he might take possession of his new kingdom. But he refused to be influenced by their entreaties, and merely promised in a vague manner that he would return as soon as he had placed France in a state of tranquillity—a promise which, it need hardly be said, he had no intention whatever of carrying out. Nor did the king show any special alacrity in repairing to France, for before reaching that country he lingered a considerable time at Vienna and Venice, trifling with the highest interests of his country, and devoted only to frivolous amusement. The Poles, however, were well rid of one of the most corrupt sovereigns of a corrupt house. In 1589 the knife of the Dominican friar terminated his life, and with it the line of the Valois.

The Poles, piqued at the contempt with which their crown had been treated, assembled at Steżycza and resolved to declare the throne vacant if the king did not return by the 12th May 1575. During the interregnum the Mongols made incursions into Podolia and Volhynia, and grievously devastated those countries. The appointed period having elapsed, Stephen Batory, prince of Transylvania, was elected, having previously stipulated to marry the princess Anne, sister of Sigismund Augustus. There were some difficulties, however, before he succeeded in obtaining the royal authority. The primate Ucharski nominated the emperor Maximilian king. This caused considerable opposition, and the city of Dantzic did not recognize the new sovereign till compelled. To conciliate the nobility

Batory was obliged to consent to some serious diminutions of the royal prerogative. This king was a great soldier, successful against both Prussians and Russians, the latter of whom he compelled, in 1582, to evacuate Livonia, which was thus again annexed to Poland. He also did much to encourage letters, having founded the university of Vilna, which has, however, been suppressed in more recent times. His great fondness for the Latin language is said by Schafarik to have had a bad effect upon Polish; for from this time may be dated the classical words and idioms which have been thrust upon the language, and have disfigured Polish more than her Slavonic sisters. It was Stephen Batory who first organized the regiments of Cossacks who play such an important part in Polish history. Before his death, foreseeing the constant anarchy which the system of elective sovereignty would cause, he in vain urged the nobility to make the crown hereditary. Sarnicki, the Polish historian, says of him—"Fuit vir tam in pace quam in bello excelso et forti animo, judicii magni, præsertim ubi ab affectibus liber erat; in victu et amictu parvus, et omni jactantia et ostentatione alienus, eruditione insigniter tinctus, sermonis Latini valde studiosus et prorsus Terentianus." It would naturally be concluded that before the election of Batory the royal power had been sufficiently curtailed, but it was to undergo further mutilations. Sixteen senators were now chosen at each diet to attend the king and give their opinion in important matters, and no decree could be issued without their consent. Besides this, in 1578 the right of final appeal to the king, which had always been a royal prerogative, was taken away. The king could now only give the ultimate decision in a small district within a certain radius of his residence. The courts exercising judgments within these narrow limits were called *Assessoria Regni*, and even these judicial powers, slight as they were, were gradually abandoned after the time of Augustus II., and were exercised by the high chancellor of the realm. The king was supposed to have some control of the courts which were governed by the *Jus Magdeburgicum*; but, Batory being busy with foreign wars, these were generally managed by the chancellor also. The palatines had the right of electing their own judges in their dietines or petty diets, who formed supreme courts of justice called *Tribunalia Regni*; here the causes of the nobles, for the peasants had no voice in the matter, were decided finally and without option of any appeal.

On the death of Batory in 1586, after many quarrels among the leading families, the throne was again brought into the market. The candidates were, among others, the archduke Maximilian of Austria; Feodore Ivanovich, the feeble Russian czar; and Sigismund, a Swedish prince, son of Catherine, sister of Sigismund Augustus. The last of the three was finally elected, although not without considerable opposition from Maximilian, who was only driven from his candidature by main force. The Zborowskis, a very powerful family always in opposition to Zamoiski, the chancellor of the kingdom, invited him. But Zamoiski defeated him at Byczyna in Silesia, and he was there made prisoner, and was only released on the promise of desisting from being a candidate. The Austrians, however, were always interfering in the affairs of Poland, and, if they could not procure the admission of any of their family to the headship of the republic, we shall observe that during four generations the house of Hapsburg furnished queens to Poland. A very serious riot occurred at the election on this occasion, as Lengnich tells us in his *Jus Publicum Regni Poloni*; the booths erected for the senators were burnt to the ground. Such proceedings were only to be expected in a country where each noble might keep as many armed retainers as he pleased.

Sigismund III.  
(1537-1632).

The new king signed the *pacta conventa*, and an alliance offensive and defensive between Poland and Sweden; the navigation of the Baltic was secured, and the debts of the nation were to be discharged. Sigismund, however, soon became unpopular among his new subjects, and among other causes of offence he violated the *pacta conventa* by marrying an Austrian princess, Anne, daughter of the archduke Charles, without their consent. In 1595, at Brześć in Lithuania, took place the so-called union of the Greek and Latin Churches, but this union was not brought about without considerable violence. The disputes between the king and the diet were destined to be renewed when (his wife being dead) he married her sister Constantia in 1605. This union was also entered into without the consent of his subjects, and caused the crop of their wrath, already full, to overflow. On this occasion Jan Zamoiski, the chancellor already mentioned, addressed a vehement oration to the king, which is quoted at full length by Lelewel, in which he brought his marriage against him among many other charges. When Zamoiski had finished, Sigismund rose from his throne in a moment of anger and seized his sword. At this gesture a murmur of indignation ran through the diet, and Zamoiski cried in the midst of the crowd, "Rex, ne move gladium; ne te Caium Cæsarem, nos Brutus sera posteritas loquatur. Sumus electores regum, destructores tyrannorum; regna, sed ne impera." A great *rokosz* or secession, as the phrase was in Polish, was the result of this. But the rebels wanted able leaders, and the king defeated them at Guzow, near Radom, on the 6th July 1607, and thus his throne, already tottering, seemed to become a little stronger. He pardoned the insurgents; and the country, on the verge of civil war, seemed pacified; but the rebellion was a fatal precedent. The most important events in this reign were the transactions which took place between Poland and Russia. The renegade monk Otrepieff personated the young Dmitri of Russia, who had been assassinated, probably by the orders of Boris Godounoff, and aspired to seat himself upon the throne of the czars. This wonderful plot was concocted at Cracow, and seems to have been a plan of the Jesuits to bring over the Russians to the Latin Church.<sup>1</sup> In 1606 the pretender was killed in a tumult, and many of the Poles who had accompanied him to Moscow were murdered. In 1617 Sigismund sent his son Władysław to Moscow, which had been taken by the Polish general Zolkiewski. Władysław was elected czar by a certain faction; but the Russians, disliking to have a heretic for their emperor, rose against the newly appointed sovereign; and the patriotism which was lacking to the boyars was found in the unselfish devotion of a provincial butcher. Russia was freed, and a new dynasty was established in the person of Michael Romanoff. Sigismund had many wars with the Turks, which led to no very important results; the great victory, however, of Chodkiewicz at Khotin (September 28, 1622) has become ever memorable in Polish annals, and has formed the subject of several poems. Lengnich, in his *Jus Publicum Regni Poloni*, tells us that in 1632 the Cossacks petitioned to be allowed to take part in the diets. Their request was refused in an insulting manner; and the Poles had soon to pay dear for their insolence. Sigismund died in 1632; his statue still ornaments the city of Warsaw, which he made the capital in the place of Cracow. He was unceasing in his efforts to extirpate Protestantism from his dominions.

The luxury of the nobles at this period has been described at great length by Lelewel. He has also much to tell us about the small armies of retainers kept up by the Poles, which it is a pity there was no statute of

maintenance, as in England, to check. These private troops, however much bravery they may have occasionally shown, prevented all unity of action. The reign of Sigismund III. was on many grounds a disastrous one for Poland, and it was a very long one. There were constant military revolts and religious tumults. The king and his Austrian wife were so foolish as to be partly drawn into the Thirty Years' War. They thought that, supported by the emperor and the king of Spain, they might be able to regain the crown of Sweden. They therefore permitted the emperor to enrol troops in Poland, and even sent him some regiments of Cossacks; they also got ready a fleet in the Baltic—strange as it may seem to hear of Poland as a naval power. All these plans, however, ended miserably. By the treaty of Malborg (Marienburg), in 1623, Sweden gained Livonia, Elbing, and part of Prussia.

He was succeeded by his son Władysław IV., who was elected by the diet. During his reign the usual wars took place with the ancient enemies of the republic,—the Swedes, Russians, and Turks. Before its close the revolt of Bogdan Chmielnicki had broken out, which cost Poland her Cossack subjects, who had been so happily gained over by the more vigorous policy of Batory. The Zaporogians, or Cossacks of the Dnieper, now transferred their allegiance to Alexis of Russia. They had long felt uncomfortable under the Polish government owing to the proselytizing tendencies of the bigoted Sigismund III. Fresh alarms were caused by the erection of the fortress of Kudak on the Dnieper, and they broke out into open rebellion. In 1638 they were deprived of the right of having a hetman; and Pawluk, their chief, was decapitated in spite of an express promise that his life should be spared. Władysław was in constant collision with his nobles. He fretted under the restrictions placed upon his power, and attempted to carry on wars without the consent of the diet. But the nobles compelled him to break all his engagements. He died at Merez in Lithuania, between Grodno and Vilna, May 20, 1648, and was succeeded by his brother John Casimir (Jan Kazimierz), the other candidates being the czar Alexis, father of Peter the Great, and Ragotzi, prince of Transylvania. One of the first acts of the new king was to endeavour to negotiate with Bogdan, but the negotiations were brought to an abrupt termination by the treachery of Wiśniowiecki, the Polish general, who fell upon the unsuspecting Cossacks while they were deliberating about the terms of the convention. After this massacre Bogdan raised another army, but was completely defeated by John Casimir at Beresteczko in 1651. The kingdom, however, was thrown into the greatest confusion by the disputes of the nobles, and all vigorous action was paralysed. The blood-stained annals of these wars are full of horrors: the population in many districts was entirely extirpated; everywhere murder and plunder were rampant; and tortures too horrible to mention were inflicted upon the unhappy prisoners.

At a diet held in 1652 a single nuntius for the first time annulled by his *liberum veto* the united resolutions of the whole assembly,—Siciński, from Upita in Lithuania, stopping the diet with the simple word "niepozwalam" (I forbid). As soon as he had uttered this ominous protest he quitted the assembly. Those who were present were puzzled as to what construction they ought to put upon such a proceeding, but Siciński had not acted without confederates on whom he could rely. An angry debate ensued, but the principle was finally carried by a majority and firmly established. Ruptures of this kind became more frequent, as Lelewel tells us, and the queen Louise Marie, who had great influence over the king, frequently made use of them. Lengnich, in his *Jus Publicum Regni Poloni* (1742), enumerates thirteen occasions on which this baleful practice

<sup>1</sup> See, however, *Roxe et Demetrios*, by A. P. Pierling, S. J. (Paris, 1873), for the contrary view.

had broken up the diet. It was not finally abolished till 1791. The reasons why it was popular have already been spoken of. Among other causes may be mentioned the anxiety of the great officers of the realm—the commander-in-chief, treasurer, marshal, and others—to be free from the control of the diet. These important functionaries held their appointments for life, and were under no supervision during the intervals between the sessions of the diet. Again, it was only before the diet that a noble accused of capital crimes could be brought to trial, for the nobility exercised, as has already been said, supreme judicial powers in their own palatinates. If, therefore, as was frequently the case, a criminal of this rank happened to be brought forward, it was very convenient for him to be able to procure a dissolution of the only tribunal by which he could be convicted. Again, it was an admirable way to oppose the levying of taxes, which could only be raised by the consent of the diet; and taxes, owing to the constant wars in which she was engaged, were very heavy in Poland. There were emissaries of foreign powers, too, who fomented these internal discords and profited by fomenting them.

The ill effects of the *liberum veto* soon began to be felt. In 1670 the members of the diet bound themselves by an oath not to make use of the privilege. In spite, however, of this resolution that very diet was brought to an end by the appeal of Zabokrzycki, the nuntius from Braclaw in

Treaty of  
Andrus-  
zowo.

In 1667, by the treaty of Andruszowo, Poland lost to Russia Smolensk, Vitebsk, Polotsk, and other towns, the Dnieper now becoming the boundary; Kieff, the interesting old historical city, was to go two years later. In the midst of all these misfortunes the exhausted country was attacked by a new enemy, Sweden, in consequence of the Polish monarch asserting a right to the Swedish crown, as the heir of the house of Vasa—a claim which he had no possibility of enforcing. Hampered as he was by a war with Russia, John could effect nothing against his new enemies, who took both Warsaw and Cracow, and ended by entirely subjugating the country, while the wretched king fled to Silesia. Although these new enemies were afterwards expelled, yet the war was protracted for some years, and ended disastrously for Poland. Charles Gustavus, the Swedish king, is said to have proposed the partition of the country; he offered Great Poland to the elector of Brandenburg, Little Poland to the duke of Transylvania, and a part of Lithuania to a Polish nobleman named Radevick. But Poland's hour had not yet come. The elector of Brandenburg procured the release of East Prussia from all seignorial rights in 1657. Livonia was also another loss, having been ceded to Sweden in 1660. An army of Cossacks and Mongols, which had invaded Podolia, was defeated by the celebrated John Sobieski, who now first appears in history and was made commander-in-chief of the Polish troops. Worn out with age, and disgusted with his repeated failures, the king abdicated in 1668. At a previous diet he had warned his turbulent subjects that the partition of the kingdom must be the inevitable consequence of their dissensions. John Casimir had already been an ecclesiastic; he had been absolved from his vows by the pope when he became a candidate for the throne. He now resolved to betake himself again to the cloister,—his wife, Louise Marie, daughter of the duke of Nevers, a woman of beauty and spirit, being dead. He took his leave of the Poles in an affectionate and dignified address, which is still preserved, and has been pronounced by Coxe to be "the finest piece of pathetic eloquence that history has ever recorded." There was something very touching in the fact that Jan Kazimierz represented the last of the Jagiellons and Vasas, the former of whom had so long ruled over Poland. He was son, as previously mentioned, of Sigismund III., and great-grand-

son of Sigismund I., whose daughter Catherine had married John, king of Sweden. Connor says, "While I was at Warsaw I spoke with several old gentlemen, who told me that Casimir, the day after his resignation, observing the people hardly paid him the respect due to a gentleman, much less to a king, seemed to have repented heartily of the folly he had committed" (i. 135). He now returned to France, a country in which some years previously he had suffered a strange captivity, having been detained in the reign of Louis XIII. while passing its coasts; but the story is too long to be narrated in these pages. Here he became abbot of St Germain and St Martin, and drew his means of subsistence from these ecclesiastical foundations; for the Poles, although to all appearance abundantly moved by his melancholy rhetoric, refused to continue his pension. Nor does he appear to have spent the short remainder of his life entirely in the cloister, as we are told that he contracted a secret marriage with an amiable widow who had formerly been a laundress. He, however, survived only four years, dying in 1672, forgotten by the world but not forgetting it,—his disease, according to some accounts, being greatly aggravated by his receiving the intelligence that Kamenets in Podolia had been ceded to the Turks. His body was afterwards brought to Cracow and buried in the cathedral. The diet, which met on his abdication, passed a decree that for the future no Polish king should be allowed to abdicate. During this reign, in the year 1658, the Socinians were banished from Poland, in consequence of which Pope Alexander II. gave to the king and his successors on the Polish throne the title *Rex Orthodoxus*. In due time three candidates for the vacant throne made their appearance—the prince of Condé, the prince of Neuburg, supported by Louis XIV., and Charles of Lorraine, who was put forward by Austria. The first of these could rely upon the cooperation of the great Sobieski, but eventually none of the three was chosen. The election fell upon a native Pole—Prince Michael Korybut Wiśniowiecki, of a noble family indeed, but so impoverished that he may be said to have had regal honours thrust upon him against his will, and we are even told that he was offered the crown half in derision. A graphic picture of this extraordinary scene is given in Pasek's contemporary memoirs. Michael soon became a mere puppet in the hands of his turbulent subjects. His reign, however, was rendered illustrious by the great successes of Sobieski against the Turks, although the Poles suffered the loss of the important town of Kamenets, and Michael, powerless to make head against them, concluded the treaty of Buczacz, by which he even stipulated to pay them tribute. By the great victory of Khotin in 1673, Sobieski did much to repair these losses, and was about to follow up his glorious campaign when he heard of the death of Wiśniowiecki at Lemberg in Galicia; so sudden was the end of Michael that some have even supposed that he was poisoned,—“by a Frenchman,” says Connor. The diet met at Warsaw; there were several candidates; and among others Charles of Lorraine and Philip of Neuburg again put forward their claims. While the nobles were still in session, Sobieski, fresh from his glorious victory, entered and proposed the prince of Condé. A stormy discussion ensued, and in the midst of it one of the nobles, Jablonowski, was heard to say, “Let a Pole rule over Poland.” The cry found a magic echo among those who were present, and the gallant Sobieski, the greatest of Polish generals, and one of the first soldiers of his time, was appointed king under the title of John III., although not without considerable opposition from Michael Pac, the general-in-chief of Lithuania, who was, however, ultimately induced to withdraw his protest. This king signed the same *pacta conventa* as the preceding monarchs; there was, however,

Michael  
Wiśni-  
owiecki  
(1669-  
73).

John III.  
(1674-  
96).

a trifling addition made to them, but that a very absurd one. To the article declaring that offices should only be conferred on native nobles it was added, "and on such only as have had their honours during three generations." The leading idea of Sobieski was to drive the Turks out of Europe, and if possible to resuscitate the Byzantine empire. He was soon roused to action by a new invasion of the Turks and Mongols, whose united armies are said to have amounted to 210,000 men,<sup>1</sup> commanded by the Seraskier Ibrahim, whose ferocious character was sufficiently indicated by his soubriquet, Shaitan or Devil. We are told that Sobieski had only 10,000 men to oppose to this vast host; he, however, set out from Lemberg, and was soon hemmed in by his adversaries at Zurawno, in Galicia, but by consummate bravery and adroitness succeeded in rescuing himself and his soldiers, even concluding a treaty with the Porte on favourable terms, by which Poland received back a part of the Ukraine and Podolia.

Siege of  
Vienna  
(1683).

Some years of peace followed, during which the king in vain endeavoured to raise supplies for an army to reconquer the provinces which Russia had appropriated. All his plans were neutralized by the absurd practice of the *liberum veto*. In 1683 the Turks made their grand invasion which they had long been preparing. After scouring the plains of Hungary, they advanced to the very walls of Vienna. The emperor Leopold at once fled with his court, but had great difficulty to avoid falling into the hands of the Mongols. The imperial party made no stay till it reached the Bavarian fortress of Passau. Quick in its track followed also the wealthier portion of the inhabitants; their selfish desertion aroused murmurs of disapprobation, and also considerably thinned the number of the population capable of bearing arms; many of these fugitives fell into the hands of the invaders, who were capable of any cruelty. The command of the city was taken by Count Stahremberg; he had already approved himself a brave soldier, and had been nominated to the post by the emperor. All classes at once—including even priests and women—laboured diligently at the fortifications, the burgo-master Von Liebenberg himself setting an excellent example. The imperial archives had already been removed; nothing now remained for the devoted city but to await the approach of the enemy. The inhabitants could see the desolated villages, and the fire and smoke of the burning cottages were conspicuous for miles around. At sunrise on July 14 the vast hordes of the invaders, a promiscuous crowd of soldiers, camp-followers, camels, and baggage-waggons made their appearance. The camp was arranged in the form of a crescent; splendid above all other things was the tent of the vizier, Kara Mustapha, made of green silk, worked with gold and silver, set with precious stones, and containing inside the holy standard of the prophet. Marvellous stories are told of the fountains, baths, gardens, and all the appliances of Oriental luxury which it contained. Many painful incidents characterized the siege before the arrival of Sobieski; a fire at one time broke out in the city, which was only suppressed with difficulty. Diseases raged among the townspeople owing to their being compelled to spend their days in such close quarters and to live chiefly upon salt meat. Relief, however, was rapidly approaching. The elector of Saxony, John George, marched out of Dresden on the 22d July with twelve thousand men and eighteen guns, and reached Krems on the 28th August. The Polish king, who had been solicited by the emperor himself, and to whom all Europe looked now as its saviour, left Cracow accompanied by his son, and succeeded in reaching the quarters of Prince Charles of Lorraine. He was to act in concert

<sup>1</sup> 80,000 Turks and 130,000 Mongols, as we are told by the Polish historians.

with a man who had been competitor with him for the Polish crown; their meeting passed off amicably, and no subsequent jealousies seem to have marred their operations. The Polish and German troops effected their junction at Krems on the Danube, near Vienna; there were about seventy-seven thousand men ready for active operations in the field. On the 12th September, after mass, Sobieski descended from the city to encounter the dense masses of the Moslems in the plains below. He appeared with his hair partly shaven in the Polish fashion, and, although plainly attired himself, was accompanied by a brilliant retinue. In front went an attendant bearing the king's arms emblazoned, and with him another who carried a plume on the point of his lance. On his left rode his son James, unfortunate in afterwards incurring the hatred of his mother, who perhaps prevented him from being elected to the throne of Poland; on his right was his old rival, Charles of Lorraine. Before the battle the king knighted his son and made a patriotic address to his troops, in which he told them that on that occasion they did not defend Vienna alone, but rather all Christendom, and that they were not fighting for an earthly sovereign but for the King of kings. The shouts of the soldiers bore to the enemy the dreaded name of Sobieski, familiar to them on many a well-fought field. He is said to have been provoked to give the order for battle by seeing Kara Mustapha, the Turkish commander, tranquilly taking coffee with his two sons in his splendid tent.

The assault was made simultaneously on the wings and centre of the enemy. The king himself dashed forward to the pasha's tent, bearing down all opposition and repeating with a loud voice, "Non nobis, non nobis, Domine exercituum, sed nomini Tuo da gloriam." "Allah!" said the Mongol khan, "the king is surely among them." In spite of the bravery of the Turks they were overpowered by the *elan* of the Poles. Six pashas were slain, and the vizier fled with the remnant of his army. The booty taken was immense. The details of the battle may be gathered from the interesting letters which Sobieski wrote to his wife in the Polish language. She was a Frenchwoman, daughter of Henri de la Grange, captain of the guard to Philip, duke of Orleans, and had been originally maid of honour to Louisa, queen of Wladyslaw IV., was then married to Count Zamoiski, and after his death became the wife of Sobieski. It is said that chiefly on her account the Polish king was induced to assist Austria. The selfish policy of Louis XIV. would have allowed this outpost of Christian Europe to be taken by the Turks, and he used all the secret springs of his diplomacy to divert Sobieski from his purpose. He had, however, given mortal offence to this ambitious woman in refusing the title of duke to her father. After the complete rout of the Moslem, Sobieski and his troops entered Vienna, and divine service was performed in the cathedral; a priest read aloud the text, "There was a man sent from God, whose name was John." In spite of his success, the brave Pole was doomed to meet with ingratitude at the hands of the emperor Leopold, and through the selfishness of his own troops and the Lithuanian contingent, who seem to have been always at cross purposes with the Poles, he was not able to follow up his victory to its legitimate end.

The king, after this brilliant achievement, showed some inclination to be reconciled to Louis XIV., but the emperor succeeded in diverting him by holding out hopes of securing the government of Moldavia and Wallachia for his son. By the treaty of Moscow, which Sobieski concluded in 1686 with Sophia, the regent of Russia, Smolensk, Severia, Tchernigoff, and Kieff were definitely annexed to the latter country. The private life of Sobieski was embittered by family dissensions; he was very much

under the influence of his wife, a woman of great beauty, but avaricious, fond of power, and revengeful. Thus the illustrious soldier had not peace in his own house, nor was he likely to meet with it in the stormy debates of the diet, several of which were broken off by the exercise of the *liberum veto*; and so wearisome had his position become that he several times thought of abdicating, and the Austrian party (such was the gratitude he met with) sought to effect this. He finally sank under an accumulation of disorders, and expired on the 17th June 1696, at his favourite castle of Willanow. Many incidents of his death-bed have been recorded by Zaluski, the bishop of Plock, which show that the king died ill at ease, being filled with the gravest apprehensions concerning the future of his country. The family is now extinct. With him sank the glory of Poland, which was rapidly hastening to its fall.

Augustus II.  
(1698-1733).

After a time the diet met as usual to elect the new sovereign. The three chief candidates were James Sobieski, the son of the late king; the prince of Condé, a nephew of Louis XIV.; and the elector of Saxony. The elector was appointed, and, in order to qualify for the throne, abjured Protestantism. In 1699, by the peace of Carlowitz, the Turks renounced all claim over the Ukraine and Podolia, but the king was foolish enough to allow himself to be drawn into a war with the Swedes, in consequence of which Cracow was taken in 1702. Charles XII. of Sweden became master of the country, and deposed the newly elected Frederick Augustus, in whose place was chosen Stanisław Leszczyński, palatine of Posen, a man of benevolence and learning. All the courts of Europe recognized this new king except the czar Peter, and when the latter defeated Charles at the battle of Poltava in 1709 Leszczyński was compelled to leave the country, and Augustus II., as he was styled, was restored. Stanisław at the approach of the Russian troops retired to Lorraine, which he governed till his death at an advanced age. In this reign Poland lost Courland, which had long been one of its fiefs, but was now seized by the Russians and given by the empress Anne to her favourite Biren. The Dissidents, as the Protestants were called, were slowly decreasing in number, and in an *émeute* which occurred at Thorn in 1724 many were cruelly put to death. A little later, in 1733, a law was passed by which they were declared incapable of holding any office or enjoying any dignity. Augustus II. died at Warsaw in the last-mentioned year. He was a contemptible king, notorious for his private vices. At the instigation of many of the Poles, Stanisław Leszczyński, who was now residing in Lorraine, and had become the father-in-law of Louis XV., was induced to return to Poland, and was elected king at Warsaw by a large majority. This election, however, was displeasing to Austria and Russia, who resolved to resist his pretensions and to secure the election of Frederick Augustus, the son of the late king. A Russian army arrived in the neighbourhood of Warsaw, and a party of the nobles opposed to the French influence proclaimed the Saxon. He accordingly swore to the *pacta conventa*, and was crowned king at Cracow in 1734. Meanwhile the unfortunate Stanisław fled to Dantzic, where he hoped to hold out till assistance should arrive from France. The city, however, was obliged to capitulate after a siege of five months; and Stanisław, after many adventures and narrow escapes, reached the Prussian dominions. In 1736 a diet of pacification was held at Warsaw, which was followed by a general amnesty. The condition of the country during this reign was deplorable, although Poland was engaged in no wars. Factions rent the government, and the peasantry, crushed and suffering, betook themselves to robbery and pillage. The king was a man of low tastes, and abandoned himself

Frederick Augustus  
(1734-63).

to pleasure. One of his favourite amusements was shooting dogs from the windows of his palace at Warsaw, in consequence of which dogs became very scarce in the city. He was too idle to learn a word of Polish, and left everything to the management of his minister Brühl. Frederick died on October 3, 1763, at Dresden, where he was buried. In 1764 Stanisław August Poniatowski was elected king, chiefly through the machinations of the Russian empress Catherine. The new monarch was a man of refined manners and elegant mind, but weak, and a mere puppet in Muscovite hands. He caused the *liberum veto* to be abolished, but it was soon restored (in 1766), in consequence, it is said, of Russian influence, as the ruin of Poland had been resolved upon. In 1768 a few patriots met at the little town of Bar in Podolia, and formed what was called the Confederation of Bar, their object being to free the country from foreign influence. Among the members of this confederation were the Pulawskis (Casimir and Joseph), Joachim Potocki, and Adam Krasinski, bishop of Kamenets. Their military operations extended over all Poland and Lithuania, but the Russian troops stationed round the capital prevented the junction of the confederates with the national army. Moreover the confederates, whose number amounted to about eight thousand fighting men, were badly organized. In spite of a few trifling successes they saw their efforts gradually growing weaker. Nor did a bold attempt to carry off the king result in success. Their party speedily broke up, and Casimir Pulawski, one of the leading spirits, left the country and joined the Americans in their War of Independence, in which he soon afterwards perished. In consequence of the efforts of these patriots the pernicious *liberum veto* was put a stop to, though afterwards for a short time restored; but the partition of the country had already been secretly agreed upon by Russia, Prussia, and Austria. The idea appears to have been first suggested by Frederick the Great. M. Rambaud, in his *Histoire de la Russie*, gives the following as the chief causes which led to the destruction of Poland, which, in addition, had always suffered from the want of natural frontiers:—

1. The national movement in Russia, which fostered the idea of recovering the provinces in the west which had formerly been Russian territory, and spoke a language but little differing from Russian. To this was to be added the fact that the majority of the inhabitants were members of the Greek Church. This feeling had already led to the conquest of some of the western provinces in the time of Alexis Mikhailovich as previously mentioned. Moreover, the members of the Greek Church were being constantly persecuted by the Jesuits, who had done so much mischief to the country.
2. The great desire of Prussia to become possessed of the lower part of the Vistula, with the towns of Thorn and Dantzic. A reason for Prussian interference was afforded by the Polish persecution of the "Dissidents," as a sample of which the cruelties committed at Thorn may be cited.
3. The general political condition of Poland—an anachronism among the nations of Europe. They had become strong by centralized power and by harmonizing their governments with the spirit of the age. In Poland there was no middle class; for the trade in the towns was in the hands of foreigners, and especially Jews.

There were to be seen a proud nobility, the members of which were engaged in constant feuds among themselves, and far below them miserable serfs deprived of all political rights. There was no national spirit in the country, no sympathy between the nobility and peasantry. It was the Jews who chiefly busied themselves with commerce; they distributed the products, selling at the same time to the serfs and their masters, and preventing the two classes of the natives of the country to a great extent from coming into contact with each other. By their efforts the economic functions of every-day life were carried on, and yet they could not be considered a real part of the nation. In the moment of danger they were not at hand to bring together distinct classes and to establish a common bond

of interest; the nation, thus consisting of men who did not understand each other, remained perplexed and divided. The peasants, who had at one time communal possession of the land, according to the old Slavonic custom, had long ago lost all their rights. Those Poles who struggled for liberty themselves were not willing to extend it to their unhappy serfs. Kosciuszko desired to see serfdom abolished; but the peasants who followed him only enjoyed their liberty during the war, and his decree of emancipation was so vaguely expressed that it was ineffectual. It is strange to think that the real liberators of the peasant were the Russians, who in the revolt of 1863 gave him a portion of the land which he cultivated.

Partition  
of the  
country.

In 1772 Prussia took the palatinates of Malborg, Pomeria, and Warmia, Culm, except Dantzic and Thorn, and a part of Great Poland; Austria took Red Russia or Galicia, with a part of Podolia, Sandomir, and Cracow; and Russia took White Russia, with all the part beyond the Dnieper. The Poles were obliged to sanction this plundering of their country in a diet held in 1778. The only real benefit conferred on the nation by this diet was the introduction of a better system of education; the Jesuits were also suppressed, and their immense estates became national property. Although the country had been mutilated in this fashion, it yet enjoyed tranquillity for a short time, and even made some material progress. Thus some useful manufactures were introduced. In 1788 a remarkable diet was opened which lasted four years,—the longest on record, for the others had only endured a few days or a few weeks at most. At this many important changes were introduced, such as the amelioration of the condition of the burghers and peasants; but it was now too late. On this occasion the *liberum veto* was decisively suppressed and the throne declared hereditary. The elector of Saxony, grandson of the wretched and incapable Augustus III., was declared the successor of Stanislaus. The Roman Catholic was to be the dominant religion, but the Dissidents were to be tolerated. The burghers were to send deputies to the diet on the same footing as the nobles. The peasants were not yet emancipated, but their condition was improved. The new constitution was finally promulgated on the 3d May 1791. The king and the two chambers took the oaths to preserve it. The country now seemed to breathe afresh, and to be established upon a new basis. But the selfishness of the Polish nobles, who had always been the evil genius of the country, overturned all the arrangements. Among the most prominent non-contenters was Felix Potocki, who was anxious to restore to the nobility the privileges they had lost by the new constitution. In concert with him were Francis Xavier Branicki and Severin Rzewuski, who sought the assistance of foreign powers, and especially Russia. These enemies of their country formed, in 1792, the Confederation of Targovica, and soon afterwards at their instigation Russian troops invaded Poland and Lithuania. The feeble king, Stanislaus Augustus, made no resistance; he signed the convention of Targovica, and the Russians occupied Warsaw. In 1793 another treaty of partition was signed, by which Prussia acquired the remainder of Great and a portion of Little Poland, and the Russian boundary was advanced to the centre of Lithuania and Volhynia. An insurrection now broke out under the leadership of Thaddeus Kosciuszko, which at first made head against the Prussians and Russians, who had invaded the country from all quarters; but the successes of the insurgents were stained by the murders committed by the popular party at Warsaw. Suwaroff now entered the country, and Kosciuszko was finally defeated and made prisoner at the battle of Maciejowice in 1794; there is no truth, however, in the assertion

that he cried out on that occasion, "Finis Poloniæ"; this he always denied till the day of his death. After storming the suburb Praga, Suwaroff took Warsaw, and the city was sacked with great cruelty. The kingdom of Poland was now at an end, and the third division took place. Austria had Cracow, with the country between the Pilica, the Vistula, and the Bug; Prussia had the capital, with the territory as far as the Niemen; and the rest went to Russia. Stanislaus resigned the crown at Grodno on April 25, 1795; he was summoned to St Petersburg, where he is said to have endured many indignities from the emperor Paul, who never allowed him to remain seated in his presence. There he died in 1798.

Many of the Poles now entered foreign services, as, for instance, the legion which followed the fortunes of France; but the fate of these exiled patriots was often a sad one. Many perished on the burning sands of St Domingo. Many were killed in the famous expedition to Moscow. The Poles looked anxiously to the success of Napoleon. But all that the conqueror did for them was to form the duchy of Warsaw, consisting of six departments—Posen, Kalisz, Płock, Warsaw, Lomza, and Bydgoszcz—with a population of more than two millions, which he united with Saxony.

A resettlement of Poland took place by the treaty of Vienna (1814). (1) Austria was to have Galicia and the salt-mines of Wieliczka. (2) Posen was to belong to Prussia. This power was also confirmed in what it had gained at the first partition. (3) The city and district of Cracow were to form an independent republic under the guarantee of the three powers. This historical town was annexed by Austria in 1846 in defiance of all international law. (4) The remainder of ancient Poland, comprising the chief parts of the recent grand-duchy of Warsaw (embracing a tract bounded by a line drawn from Thorn to near Cracow on the west, to the Bug and Niemen in the east), reverted to Russia, and was to form a constitutional kingdom subject to the czar. This constitution, considering the circumstances, was a very liberal one. Poland was to be governed by responsible ministers, a senate, and a legislative chamber. There were to be a national army under the national flag and a separate budget. Polish was to be the official language; personal liberty and the freedom of the press were also guaranteed. It was obvious from the first that it would be difficult to unite a country with such a liberal constitution to another still governed by a patriarchal despotism. Zajacek was named viceroy, and the grand-duke Constantine, brother of the emperor Alexander, took the command of the army.

The rebellions of the Poles in 1830 and 1863 more properly belong to Russian history; perhaps, however, a few facts connected with them may be appropriately introduced here.

Considering the delicate position of affairs in Russian Poland, things had worked fairly well. The impulse to the Polish revolution was undoubtedly given by the French. It was begun by some students, who hoped to seize the grand-duke Constantine at his residence, Belvedere, in the vicinity of Warsaw. In the evening of November 29, 1830, they accordingly proceeded to the palace, but did not succeed in capturing the grand-duke. The city, however, rose, the troops fraternized with the people, and the chief command was entrusted to General Chlopicki, a veteran of the wars of Napoleon. Early in 1831 a large Russian army, commanded by Diebitsch, advanced to reduce them to submission. Chlopicki laid down his dictatorship, but the Poles pursued the insurrection with vigour under the command of Prince Adam Czartoryski. They were disappointed in their hopes of assistance from foreign powers. On the 8th September Warsaw surrendered to

Resettle-  
ment by  
treaty of  
Vienna.

Rebellion  
of 1830.

Parkowitch, who had taken the command, Diebitsch having died of cholera (June 10th), and a few weeks afterwards the grand-duke Constantine died at Vitebsk. On February 26, 1832, Poland was declared a Russian province.

*Rebellion of 1831.* No other outbreak occurred till 1863, but for some time previously the country had been disturbed. On the 29th November 1830, on the occasion of the thirtieth anniversary of the revolution of 1830, many political manifestations took place both in the churches and streets, and portraits of Kosciuszko and Kilinski, a patriot of the time of the last partition, were distributed. Some riots took place, and unfortunately several persons were killed. These proceedings were followed by concessions from the emperor Alexander, who established municipal institutions in Warsaw and the chief cities of the kingdom. The Russian czar was acting under the advice of Wielopolski, a Pole, who was appointed director of public instruction and worship. Riots, however, still continued, and in 1832 the grand-duke Constantine was named viceroy. On the night of January 15, 1833, a secret conscription was held, and the persons suspected of being most hostile to the Government were dragged from their beds and enlisted as soldiers. Immediately after this the insurrection broke out, which was directed by a secret committee (*Rząd*), the proceedings of which were as mysterious as those of the *Fehmgericht*. Soon after bands of rebels began to make their appearance in the Polish forests. There were, however, no regular battles between the Russian troops and the Poles,—only guerilla fighting, in which the Poles, under the greatest disadvantages, showed splendid heroism. The secret emissaries of the revolutionary Government, armed with daggers, succeeded in putting to death many Russian spies—not the least memorable case being that of the Jew Hermani, stabbed while on the staircase of the *Hôtel de l'Europe* at Warsaw. On the other hand the chiefs of the insurgents captured were shot or hanged. Langiewicz held out for some time, but was defeated by the Russians, and succeeded in making his escape into Galicia. A reign of terror was inaugurated by General Mouravieff, and all attempts at reconciliation made by the great powers of Europe were useless. By May 1864 the rebellion was quite suppressed, and it will be seen by the results that it cost Poland dear. The kingdom of Poland now ceased to exist; it has been parcelled out into six governments. The Russian language was ordered to be used in all public documents instead of Polish, and the university of Warsaw has been Russified, all lectures now being delivered in that language.

We have not dwelt upon the terrible massacres of the Polish nobles by the peasants in Galicia in 1846, said to have been instigated by the Austrian Government. This province has been tolerably quiet since, but the Poles have to struggle with the large Ruthenian or Red-Russian population, speaking a different language, and adherents of the Greek Church or Uniates.

In Prussian Poland, though it is but fair to add that we hear no stories of massacres, the Germanization of the province has been more complete. Posen will soon be lost as a Polish town, and many historical places have had their names obliterated for such substitutes as Bismarcksdorf and Sedan.

#### POLISH LITERATURE.

The Polish Language, according to the latest statistics, is still spoken by nearly ten millions of people, distributed, according to the *Revue Slave* (Warsaw, 1878, vol. i. p. 78), as follows:—in Russia, 4,640,000; in Austria, 2,444,200; in Prussia, 2,405,800; in Turkey, 10,000. It belongs to the western branch of the Slavonic tongues, and exhibits

the closest affinities with the Czech or Bohemian and Lusatian Wendish (see SLAVONIC LANGUAGES). Unlike the people of other Slavonic countries, the Poles are comparatively poor in popular and legendary poetry, but such compositions undoubtedly existed in early times, as may be seen by the writings of their chroniclers; thus Gallus translated into Latin a poem written on Boleslaw the Brave, and a few old Polish songs are included in Wojcicki's *Library of Ancient Writers*. A great deal of the early literature written in Poland is in Latin. The earliest specimen of the Polish language is the so-called *Psalter* of Queen Margaret, discovered in 1826 at the convent of St Florian. The date of the MS. appears to be the middle of the 14th century, and probably in its present form it is only a copy of a much older text; there is also a translation of the fiftieth psalm belonging to the 13th century.<sup>1</sup> The ancient Polish hymn or war song, "*Piesn Bogu Rodzica*," was an address to the Virgin, sung by the Poles when about to fight. The oldest manuscript of this production is dated 1408, and is preserved at Cracow. By a legend which subsequently grew up the composition of it was assigned to St Adalbert. John Lodzia, bishop of Posen from 1335 to 1346, composed several religious songs in Latin.

The next monument of Polish literature to which we come is the Bible of Queen Sophia or Bible of Szaroz-patak. It is imperfect, and only contains the early books, viz., the Pentateuch, Joshua, Ruth, and Kings; there are, however, fragments of three others. It is said to have been written for Sophia, the fourth wife of Jagiello, about the year 1455. It has been edited with great care by Matecki. Five religious songs in Polish dating from the 15th century have been preserved; they are ascribed to Andrew Slopuchowski, prior of the monastery of the Holy Cross on Lysa Góra. There is also the fragment of a hymn in praise of Wickliffe. To these fragments may be added the prayer book of a certain Wacław, a sermon on marriage, and some Polish glosses. These are all the existing memorials of the Polish language before the 16th century.

Perhaps a few words should be said concerning the Latin writers in Poland. Martin Gallus lived in Poland between 1110 and 1135. From his name he has been supposed by some to have been a Frenchman, and we must remember that Poland swarmed at that time with foreign ecclesiastics. Lelewel, the Polish historian, considers that it is merely a translation into Latin of some such name as *Kura*, signifying "a fowl." Others suppose him to have been an Italian, or a monk from the convent of St Gall in Switzerland. He has plenty of legends to tell us, and writes altogether in a poetical style, so that his prose seems to fall into rhythm unconsciously. His quotations from the classics, Sallust, Lucan, and others, show the extent of his reading. Gallus was followed by Matthew Cholewa and Vincent Kadlubek, two bishops of Cracow, and Bogufal or Boguchwal (Gottlob), bishop of Posen, who all used Latin. The work of Kadlubek is more ornate in diction than that of Bogufal and for a long time enjoyed great popularity. He was born in 1160, educated at the university of Paris, and died in Poland in 1223, as a Cistercian monk. His Latin, like that of Gallus, is far from classical, but he writes with spirit and throws a good deal of light upon the events of his time. The education of the country was wholly in the hands of the ecclesiastics, many of whom were foreigners. In this way we must explain the great prevalence of the Latin language. Such a system would be sure to stifle all national outgrowth, and accordingly we have among the

<sup>1</sup> The *Psalter* is called after Margaret, the first wife of King Louis, who died in 1349, by a mere conjecture. Caro thinks it more probable that the book belonged to Mary, his daughter.

Poles none of those early monuments of the language which other countries boast. For instance, there are no *byliny* or legendary poems, such as are found among the Russians, although many passages in the ancient chroniclers from their poetical colouring seem to be borrowed from old songs or legends, and the first verses of some of these compositions have been preserved. Mention may here be made of other chroniclers such as Martin the Pole (Polonus), who died in 1279 or 1280, and Jan of Czarnkow, who died in 1389; the latter was the historian and panegyrist of Kazimierz the Great. With the reign of Kazimierz III. (1333-1370) must be associated the statutes of Wislica. Jadwiga, the wife of Jagiello, was mainly instrumental in creating the university of Cracow, which was not founded, however, till 1400. In this institution for many years all the great men of Poland were trained—among others Gregory of Sanok, Dlugosz, and Copernicus. Kazimierz the Great may be said to have laid the foundation of this university. Having obtained the consent of Pope Urban V., he established at Cracow a *studium generale* on the model of the university of Bologna. It consisted of three faculties—Roman law, medicine, and philosophy. But the aristocratic youth still preferred frequenting the universities of Prague, Padua, and Paris, and accordingly the newly-founded *studium* languished. Jadwiga, however, obtained from Boniface IX. permission to create a new chair, that of theology; and the university of Cracow was remodelled, having been reorganized on the same basis as that of Paris. Another university was founded later at Vilna by Batory, and one at Zamosc by the chancellor Zamoiski. There were also good schools in various places, such as the Collegium Lubrańskiego of Posen and the school of St Mary at Cracow. In the year 1474 a press was set up in the latter city, where Günther Zainer printed the first book. The first press from which books in the Polish language appeared was that of Hieronymus Wietor, a Silesian, who commenced publishing in 1515. A few fragments printed in Polish had appeared before this, as the Lord's Prayer in the statutes of the bishops of Breslau in 1475, the story of Pope Urban in Latin, German, and Polish in 1505, &c.; but the first complete work in the Polish language appeared from the press of this printer at Cracow in 1521, under the title *Speeches of the Wise King Solomon*. The translation was executed by Jan Koszycki, as the printer informs us in the preface, and the work is dedicated to Anna Wojnicka, the wife of a castellan. In 1522, a Polish translation of Ecclesiastes appeared from that press, and before the conclusion of that year *The Life of Christ*, with woodcuts, translated into Polish by Balthasar Opec. Many other presses were soon established. Printers of repute at Cracow, during the 16th and beginning of the 17th century, were Sybeneicher and Piotrkowczyk.

Dlugosz. Little as yet had been produced in Polish, as the chroniclers still adhered to Latin; and here mention must be made of Jan Dlugosz, who called himself Longinus. He was bishop of Lemberg, the capital of Galicia, and has left us a very valuable history which has merits of style and shows considerable research. So anxious was Dlugosz to make his work as perfect as he could that he learned Russian so as to be able to read the *Chronicle* of Nestor. The best part of his book is that which treats of the period between 1386 and 1480. About 1500 was written an interesting little work entitled "Memoirs of a Polish Janissary" (*Pamiętniki Janczara Polaka*). Although written in the Polish language, it was probably the production of a Serb, Michael Konstantinovich of Ostrovitz. He was taken prisoner by the Turks in 1455 and served ten years among the Janissaries, after which he escaped into Hungary. About this time also flourished Nicholas Copernicus, a native of Thorn, one of the few

Poles who have made themselves known beyond the limits of their country.

The Poles call the period between 1548 and 1606 their golden age. Poland was the great land of eastern Europe, and owing to the universal toleration encouraged by the Government Protestantism was widely spread. Many of the chief nobility were Calvinists, and the Socini came to reside in the country. All this, however, was to pass away under the great Jesuit reaction. At Rakow in Poland was published the catechism of the Socinian doctrines in 1605. The Jesuits made their appearance in Poland in 1564, and soon succeeded in getting the schools of the country into their hands. Besides extirpating the various sects of Protestants, they also busied themselves with destroying the Greek Church in Lithuania. Latin poetry was cultivated with great success by Clement Janicki (1516-1543), but the earliest poet of repute who wrote in Polish is Rej of Naglowice (1505-69). After a somewhat idle youth he betook himself to poetry. He was a Protestant, and among other religious works translated the Psalms. His best work was *Zwierciadko albo zywot Poczciwego Czlowieka* ("The Mirror or Life of an Honourable Man"),—a somewhat tedious didactic piece. He was also the author of a kind of play—a mystery we may term it, and productions of this sort seem to have been common in Poland from a very early time—entitled *Life of Joseph in Egypt*. This piece is interesting merely from an antiquarian point of view; there is but little poetry in it. It teems with anachronisms; thus we have mention of the mass and organs, and also of a German servant.

Jan Kochanowski (1530-1584), called the prince of Polish poets, came of a poetical family, having a brother, a cousin, and a nephew who all enriched the literature of their country with some productions. Kochanowski studied for some time at the university of Padua, and also resided in Paris, where he made the acquaintance of Ronsard, then one of the most celebrated poets. He exercised his talents in various ways; thus he has left *The Game of Chess*, an imitation of Vida, and *Proporzec albo Hold Pruski* ("The Standard or Investiture of Prussia"), where he describes the fealty done by Albert of Brandenburg to Sigismund Augustus. He also wrote the first regular play, and executed a translation of the Psalms. The title of his play—a piece of one act, with twelve scenes—is *The Despatch of the Greek Ambassadors*. It is written in rhymeless five-foot iambics, and is altogether a product of the Renaissance, reminding us of some of the productions of George Buchanan. Rhyme is employed in the choruses only. It was acted on the marriage of the chancellor Jan Zamoiski with Christine Radziwilt, in the presence of King Stephen and his wife, at Ujazdowo near Warsaw, in 1578. The poet's most popular work, however, is his *Treny* or "Lamentations," written on the death of his daughter Ursula. These beautiful elegies have been justly praised by Mickiewicz; they are enough to raise Kochanowski far above the level of a merely artificial poet. Besides poems in Polish, he also wrote some in Latin. It will be observed that we get this double-sided authorship in many Polish writers. They composed for an exclusive and learned circle, certainly not for the Jew, the German trader of the town, or the utterly illiterate peasant. It may be said with truth of Kochanowski that, although the form of his poetry is classical and imitated from classical writers, the matter is Polish, and there is much national feeling in what he has left us. Mention must also be made of his epigrams, which he styled "Trifles" (*Fraszki*); they are full of spirit and geniality. Stanislaus Grochowski (1554-1612) was a priest; but his poetry is of little merit, although he was celebrated in his time as a writer of panegyrics. His satire *Babie Kolo* ("The Women's Circle") gave offence on account

of its personalities. A great partisan of the Catholics in the time of Sigismund III. was Caspar Miaskowski, whose *Wakula Włoszomowski* ("Farewell to his Native Country") deserves mention. Szarzyński, who died young in 1581, deserves notice as having introduced the sonnet to the Poles. This species of poetry was afterward to be carried to great perfection by Mickiewicz and Gaszynski.

**Szymonowicz** (1554-1624) was a writer of good pastorals. Although they are imitated from classical writers, he has introduced many scenes of national life, which he describes with much vigour. Among the best are "The Lovers," "The Reapers," and "The Cake" (*Kotac*). Mickiewicz is very loud in his praise, and considers him one of the best followers of Theocritus. The condition, however, of the Polish peasants was too miserable to admit of their being easily made subjects for bucolic poetry. There is an artificial air about the idyls of Szymonowicz which makes one feel too keenly that they are productions of the Renaissance; one of their best features is the humane spirit towards the miserable peasantry which they everywhere display. Another excellent writer of pastorals was Zimorowicz, a native of Lemberg, who died at the early age of twenty-five. Some of his short lyrics are very elegant, and remind us of Herrick and Carew,—e.g., that beginning "Ukochana Lancelloto! Ciebie nie proszę o złoto." Another writer of pastorals, but not of equal merit, was Jan Gawinski, a native of Cracow. Some good Latin poetry was written by Casimir Sarbiewski, better known in the west of Europe as Sarbivius (d. 1640). He was considered to have approached Horace more nearly than any other modern poet, and a gold medal was given him by Pope Urban VIII. Martin Kromer (1512-1589) wrote a history of Poland in thirty books, and another volume, giving a description of the country and its institutions,—both in Latin. The history is written in an easy style and is a work of great merit. A poet of some importance was Klonowicz (1545-1602), who Latinized his name into *Aceruus*, *Akon* being the Polish for maple, and wrote in both Latin and Polish. Sometimes he is descriptive, as in his Polish poem entitled *Fliis* ("The Boatman"), in which he gives a detailed account of the scenery on the banks of the Vistula. There is some poetry in this composition, but it alternates with very prosaic details. In another piece, *Rhorolania*, in Latin, he describes the beauties of Galicia. Occasionally he is didactic, as in *Worek Judaszow* ("The Bag of Judas") and *Victoriu Deorum*, where, under the allegory of the gods of Olympus, he represents the struggles of parties in Poland, not without severely satirizing the nobility and ecclesiastics. A curious work called *Quincunx*, written by Orzechowski, is concerned with religious polemics. Andrew Modrzewski, a Protestant, in his work *De Republica Emendanda* (1551), recommended the establishment of a national church which should be independent of Rome, something upon the model of the Anglican.

**Skarga.** A florid Jesuitical style of oratory became very popular in the time of Sigismund III., not without rhetorical power, but frequently becoming tawdry. The chief representative of this school was Peter Skarga, one of the main agents in extirpating Calvinism in Poland and the Greek Church in Lithuania. Among his numerous writings may be mentioned *Lives of the Saints*, *Discourses on the Seven Sacraments*, and especially his sermons preached before the diet, in which he lashed the Poles for their want of patriotism and prophesied the downfall of the country. Mecherzynski, in his "History of Eloquence in Poland" (*Historia Wymowy w Polsce*), especially praises his two funeral sermons on the burial of Anna Jagiellonka, widow of Stephen Batory, and Anna of Austria, first wife of

Sigismund III. Besides the Latin histories of Wapowski and Gwagnin (Guagnini, of Italian origin), we have the first historical work in Polish by Martin Bielski, a Protestant, viz., *Kronika Polska*, which was afterwards continued by his son. The author was born in 1495 on his father's estate, Biała, and was educated, like so many other of his illustrious contemporaries, at the university of Cracow. He lived to the age of eighty; but, however great were the merits of his *Chronicle*, it was long considered a suspicious book on account of the leanings of the author to Calvinism. After his death his work was continued by his son Joachim (1540-1599). There is also a *Chronicle* by Bartholomew Paprocki. In 1582 was also published the *Chronicle* of Strykowski, full of curious learning, and still of great use to the student of history. Five years later appeared the *Annales Poloniae* of Sarnicki. The last three works are in Latin.

A few words may be said here about the spread of Protestantism in Poland, which is so intimately mixed up with the development of the national language. The doctrines of Huss had entered the country in very early times, and we find Polish recensions of Bohemian hymns; even the hymn to the Virgin previously mentioned is supposed to have a Czech basis. The bishops were soon active against those who refused to conform to the doctrines of the Roman Church. Thus we find that Bishop Andrew of Brin seized five Hussite priests and caused them to be burnt in the market of Posen in 1439. A hundred years afterwards a certain Katharina Malcher, on account of her Utraquist opinions, was condemned by Gamrat, the bishop of Cracow, to be burnt, which sentence was accordingly carried out in the ragmarket at Cracow. As early as 1530 Lutheran hymns were sung in the Polish language at Thorn. In Königsberg John Seklucyan, a personal friend of Luther, published a collection of *Christian Songs*. He was born in Great Poland, and was at first a Roman Catholic priest in Posen, but afterwards embraced the Protestant faith and was invited by Duke Albert as a preacher to Königsberg, where he died in 1578. He executed the first translation of the New Testament in 1551. Four years afterwards appeared a complete Polish Bible published by Scharffenberg at Cracow. In 1553 appeared at Brześć the Protestant translation of the whole Bible made by a committee of learned men and divines, and published at the expense of Nicholas Radziwill, a very rich Polish magnate who had embraced the Protestant doctrines. This book is now of great rarity because his son Christopher, having been induced to become a Roman Catholic by the Jesuit Skarga, caused all copies of his father's Bible which he could find to be burnt. One, however, is to be seen in the Bodleian Library, and another in the library of Christ Church, at Oxford. A Socinian Bible was issued by Simon Budny in 1570 at Nieśwież, as he professed to find many faults in the version issued under the patronage of Radziwill; in 1597 appeared the Roman Catholic version of the Jesuit Wujek; and in 1632 the so-called Dantzic Bible, which is in use among Protestants and is still the most frequently reprinted.

Up to this time Polish literature, although frequently rhetorical and too much tinctured with classical influences, had still exhibited signs of genius. But now, owing to the frivolous studies introduced by the Jesuits, the so-called macaronic period supervened, which lasted from 1606 to 1764, and was a time of great degradation for the language and literature. The former was now mixed with Latin and classical expressions; much of the literature consists of fulsome panegyric, verses written on the marriages and funerals of nobles, with conceits and fantastic ideas, devoid of all taste, drawn from their

coats of arms. The poets of this period are, as may be imagined, in most cases mere rhymsters; there are, however, a few whose names are worth recapitulating, such as Wacław Potocki (c. 1622-c. 1696), now known to have been the author of the *Wojna Chocimska*, or "War of Khotin," the same campaign which afterwards formed the subject of the epic of Krasicki. At first the author was supposed to have been Andrew Lipski, but the real poet was traced by the historian Szajnoch. The epic, which remained in manuscript till 1850, is a genuine representation of Polish life; no picture so faithful appeared till the *Pan Tadeusz* of Mickiewicz. Moreover Potocki had the good taste to avoid the macaronic style so much in vogue; his language is pure and vigorous. He does not hesitate to introduce occasionally satirical remarks on the luxury of the times, which he compares, to its disadvantage, with the simplicity of the old Polish life. There is also another poem attributed to Potocki called the *New Mercury*. In one passage he censures King Michael for ceding Podolia to the Turks. Samuel Twardowski (1600-1660) was the most prolific poet of the period of the Vasas. His most important poem is *Władysław IV., King of Poland*, in which he sings in a very bombastic strain the various expeditions of the Polish monarch. A bitter satirist appeared in the person of Christopher Opaliński (1609-1656). His works were published under the title of *Juvenalis Redivivus*, and, although boasting but little poetical merit, give us very curious pictures of the times. Vespasian Kochowski (born between 1630 and 1633, died in 1699) was a soldier-poet, who went through the campaigns against the Swedes and Cossacks; he has left several books of lyrics full of vivacity. Another poet was Andrew Morsztyn (born about 1620, died about the commencement of the 18th century), an astute courtier, who was finance minister (*podskarbi*) under John Casimir, and was a devoted adherent of the French party at court, in consequence of which, in the reign of Sobieski, he was compelled to leave his native country and settle in France (see p. 290). His poems are elegant and free from the conceits and pedantry of the earlier writers. In fact, he introduced into Poland the easy French manner of such writers as Voiture. He translated the *Cid* of Corneille, and wrote a poem on the subject of Psyche, based upon the well-known Greek myth. History in the macaronic period made a backward step: it had been written in the Polish language in the golden age; it was now again to take a Latin form, as in the *Chronica Gestarum in Europa Singularium* of the ecclesiastic Paul Piasecki (1580-1649), who is an authority for the reigns of Sigismund III. and Władysław IV., and Rudawski, who describes events from the accession of John Casimir to the peace of Oliwa (1648-1660); and as valuable materials for history may be mentioned the five huge volumes of Andrew Chrysostom Załuski (1711), bishop of Warmia. This work is entitled *Epistolæ Historico-Familiares*. It would be impossible to recapitulate here the great quantity of material in the shape of memoirs which has come down, but mention must be made of those of John Chrysostom Pasek, a nobleman of Masovia, who has left us very graphic accounts of life and society in Poland; after a variety of adventures and many a well-fought battle, he returned to the neighbourhood of Cracow, where he died between 1699 and 1701. Some of the most characteristic stories illustrating Polish history are drawn from this book. A later period, that of the miserable epoch of Augustus III., is described very graphically in the memoirs of Matuszewicz, first edited by Pawinski at Warsaw in 1876. Relating to the same period are also the memoirs of Bartholomew Michalowski (*Pamiętniki Bartłomieja Michałowskiego*). A curious insight into the course of education which a young Polish

nobleman underwent is furnished by the instructions which James Sobieski, the father of the celebrated John, gave to Orzechowski the tutor of his sons. This has been twice printed in comparatively recent times (*Instrukcja Jakóba Sobieskiego kasztelana Krakowskiego danu panu Orzechowskiemu ze strony synów*, Vilna, 1840). The old gentleman in his aristocratic imperiousness frequently reminds us of the amusing directions given by Sir John Wynne to his chaplain, quoted in Pennant's *Tour in Wales*.

A *History of the Lithuanians* in Latin was published by the Jesuit Kojałowicz; the first volume appeared at Dantzig in 1650. A valuable work on the condition of Poland was written by Stanisław Leszczyński, who was twice chosen king, entitled *Głos wolny wolność ubezpieczający* ("A Free Voice Guaranteeing Freedom"), where he tells the Poles some homely and perhaps disagreeable truths illustrating the maxim *Summa libertas cito perire volentibus*.

A notable man was Joseph Andrew Załuski, bishop of Zamość, Kieff, a Pole who had become thoroughly Frenchified,—so much so that he preached in French to the fashionable congregations of Warsaw. He collected a splendid library of about 300,000 volumes and 15,000 manuscripts, which he bequeathed to the Polish nation; but it was afterwards carried off to St Petersburg, where it formed the foundation of the imperial public library. According to Nitzschmann in his *Geschichte der Polnischen Literatur*—a work which has been of service in the preparation of this article—the books were transported to Russia very carelessly, and many of them injured by the way. It was especially rich in works relating to Polish history. Konarski edited in six volumes a valuable work entitled *Volumina Legum*, containing a complete collection of Polish laws from the time of the statute of Wislica. He did much good also in founding throughout the country schools for the education of the sons of the upper classes, but as yet nothing had been done for popular education properly so-called. About the close of this period we have some valuable writers on Polish history, which now began to be studied critically, such as Hartknoch in his *Alt- und Neues Preussen* (1684), a work in which are preserved interesting specimens of the old Prussian language, and Lengnich (1689-1774), author of the valuable *Jus Publicum Regni Poloniarum*, which appeared in 1742.

We now come to the reign of the last Polish king, Stanisław Poniatowski, and the few quiet years before the final division of the country, during which the French taste was all-powerful. This is the second great period of the development of Polish literature, which has known nothing of mediæval romanticism. The literature of the first or Renaissance period gives us some good poets, who although occasionally imitators are not without national feeling, and a goodly array of chroniclers, most of whom made use of Latin. In the second or French period we get verse-makers rather than poets, who long to be Frenchmen, and sigh over the barbarism of their country; but the study of history in a critical spirit is beginning under the influence of Naruszewicz, Albertrandi, and others. In the third period, that of modern romanticism, we get true nationalism, but it is too often the literature of exile and despair. Here may be mentioned, although living a little time before the reign of Stanisław, a Polish poetess, Elizabeth Drużbańska (1695-1760), whose writings show a feeling for nature at a time when verse-making of the most artificial type was prevalent throughout the country. The portrait prefixed to the Leipsic edition of her works is a striking one, representing a handsome, intellectual-looking woman, dressed in the garb of some religious order. Her *Life of David* in verse appears tedious, but many of the descriptions in the *Seasons*

are elegant. Unfortunately she introduces Latinisms, so that her Polish is by no means pure. A national theatre was founded at Warsaw in 1765 under the influence of the court, but it was not till long afterwards that anything really national connected with the drama appeared in Poland. Thomas Kajetan Węgierski, who was chamberlain to the king, enjoyed a considerable reputation among his countrymen for his satirical writing. He was a kind of Polish Churchill, and like his English parallel died young (1755-1787). His life also appears to have been as irregular as Churchill's. In consequence of an attack on the empress of Russia, he was compelled to leave Poland, and accordingly made a tour in Italy, France, America, and England, dying at Marseilles at the early age of thirty-three. His poetry shows the influence of the French taste, then prevalent throughout Europe. In times of great national disasters he deserves to be remembered as a true patriot; but the spirit of his poetry is altogether unwholesome. It is the wailing cry of a moribund nation. The great laureate of the court of Stanislaus was Trembecki (1722-1812), whose sympathies were too much with the Russian invaders of his country. He was little more than a fluent poetaster, and is now almost forgotten. One of his most celebrated pieces was *Zofjanka*, written on the country seat of Felix Potocki, a Polish magnate, for this was the age of descriptive as well as didactic poetry. Perhaps the English gave the hint in such productions as "Cooper's Hill." The old age of Trembecki appears to have been ignoble and neglected; he had indeed "fallen upon evil days and evil tongues"; and when he died at an advanced age all the gay courtiers of whom he had been the parasite were either dead or had submitted to the Muscovite yoke. He comes before us as a belated epicurean, whose airy trides cannot be warbled in an atmosphere surcharged with tempests and gunpowder. The end of the 18th century was not the period for a court poet in Poland.

**Krasicki.** The most conspicuous poet, however, of the time was Ignatius Krasicki, bishop of Warmia (1735-1801). He was the friend of Frederick the Great and a prominent member of the king's literary club at Sans Souci. Krasicki wrote an epic on the war of Khotin,—the same as had furnished the subject of the poem of Potocki, of which Krasicki in all probability had never heard, and also that of the Dalmatian Gundulić. Krasicki's poem is at best but a dull affair, in fact a pale copy of a poor original, the *Henriade* of Voltaire. His mock heroics are, to say the least, amusing, and among these may be mentioned *Mysiejs*, where he describes how King Popiel, according to the legend, was eaten up by rats. His *Monachomachia* is in six cantos, and is a satire upon the monks. The bishop was also the writer of some pretty good comedies. In fact most styles of composition were attempted by him,—of course satires and fables among the number. He presents himself to us much more like a transplanted French abbé than a Pole. In the year 1801 he travelled to Berlin, and died there after a short illness. Among his other works the bishop published in 1781-82 in two volumes a kind of encyclopædia of *belles lettres* entitled *Zbiór Wiadomości*. His estimates of various great poets are not very accurate. Of course he finds Shakespeare a very "incorrect" author, although he is willing to allow him considerable praise for his vigour. Another bishop-poet was Adam Naruszewicz. The existence of so many ecclesiastical writers was a natural feature in Polish literature; they formed the only really cultured class in the community, which consisted besides of a haughty ignorant nobility living among their serfs, and (at a vast distance) those serfs themselves, in a brutalized condition. Burghers there were, properly speaking, none, for most of the citizens in

the large towns were foreigners governed by the *Jus Magdeburgicum*. Naruszewicz has not the happy vivacity of Krasicki; he attempts all kinds of poetry, especially satire and fable. He is at best but a mediocre poet; but he has succeeded better as a historian, and especially to be praised is his "History of the Polish Nation" (*Historia Narodu Polskiego*), which, however, he was not able to carry further than the year 1386. He also wrote an account of the Polish general Chodkiewicz and translated Tacitus and Horace. Interesting memoirs have been published by Kilinski, a Warsaw shoemaker, and Kosmian, state referendary, who lived about this time and saw much of the War of Independence and other political affairs. Among the smaller poets of this period may be mentioned Karpiński (1741-1828), a writer of sentimental elegies in the style then so very much in fashion, and Książnin, who nourished his muse on classical themes and wrote some odes; but his poetry is not of a high order. He was the court poet of Prince Adam Czartoryski at Pulawy, and furnished odes in commemoration of all the important events which occurred in the household. He lost his reason on the downfall of Poland, and died after eleven years' insanity in 1807. Julian Ursin Niemcewicz (1757-1841) was one of the most popular of Polish poets at the commencement of the present century (see NIEMCEWICZ). His most popular work is the "Collection of Historical Songs" (*Spiewy Historyczne*), where he treats of the chief heroes of Polish history. Besides these he wrote one or two good plays, and a novel in letters, on the story of two Jewish lovers. John Paul Woronicz (1757-1829) born in Volhynia, and at the close of his life bishop of Warsaw and primate of Poland, was a very eloquent divine, and has been called the modern Skarga. A valuable worker in the field of Slavonic philology was Linda, the author of an excellent Polish dictionary in six volumes. For a long time the cultivation of Polish philology was in a low state, owing to the prevalence of Latin in the 17th century and French in the 18th. No Polish grammar worthy of the name appeared till that of Kopczynski at the close of the 18th century, but the reproach has been taken away in modern times by the excellent works of Małeckie and Malinowski. Rakowiecki, who edited the *Russkaia Pravda*, and Maciejowski (who died in 1883, aged ninety), author of a valuable work on Slavonic law, may here be mentioned. Here we have a complete survey of all the leading codes of Slavonic jurisprudence. At a later period (in 1856) appeared the work of Helcel, *Starożytne prawa polskiego pomniki* ("Ancient Memorials of Polish Law"). Aloysius Feliński (1771-1820) produced an historical tragedy, *Barbara Radziwiłł*, and some good comedies were written by Count Alexander Fredro (1793-1876). In fact Fredro may be considered the most enterprising writer for the stage which Poland has produced. He introduced genuine comedy among his countrymen. The influence of Molière can be very clearly seen in his pieces; his youth was spent chiefly in France, where he formed one of the soldiers of the Polish legion of Napoleon and joined in the expedition to Russia. His first production was *Pan Geldhab*, written in 1819 and produced at Warsaw in 1821. From 1819 to 1835 he wrote about seventeen pieces and then abandoned publishing, having taken offence at some severe criticisms. At his death he left several comedies, which were issued in a posthumous edition. There is a good deal of local colouring in the pieces of Fredro; although the style is French, the characters are taken from Polish life. From him may be said to date the formation of anything like a national Polish theatre, so that his name marks an epoch. The Poles, like many of the other nations of Europe, had religious plays at an early period. They were originally

performed in churches; but, Pope Innocent III. finding fault with this arrangement, the acting was transferred to churchyards. Mention has already been made of plays written by Rej and Kochanowski; they are mere fruits of the Renaissance, and cannot in any way be considered national. The wife of John Casimir, a Frenchwoman, Marie Louise, hired a troop of French actors and first familiarized the Poles with something which resembled the modern stage. The Princess Franciszka Radziwiłł composed plays which were acted at her private residence, but they are spoken of as inartistic and long and tedious. The national theatre was really founded in the reign of Stanislaus Augustus; and good plays were produced by Bohomolec, Kamiński, Kropiński, Boguslawski, Zabłocki, and others. Perhaps, however, with the exception of the works of Fredro, the Poles have not produced anything of much merit in this line. A great statesman and writer of the later days of Polish nationality was Kołłątaj, born at Sandomir in 1750. He was a man of liberal sentiments, and, had his plans been carried out, Poland might have been saved. He wished to abolish serfdom and throw open state employments to all. The nobility, however, were too infatuated to be willing to adopt these wise measures. Like the French aristocrats with the reforms of Necker, they would not listen till ruin had overtaken them. During the last war of Poland as an independent country Kołłątaj betook himself to the camp of Kosciuszko, but when he saw that there was no longer hope he went to Galicia, but was captured by the Austrians and imprisoned at Olmütz till 1803. He died in 1812. An active co-operator with Kołłątaj was Salesius Jezierski, who founded clubs for the discussion of political questions, and Stanislaus Staszic, who did much for education and improved the condition of the university of Warsaw.

Roman-  
ticism.

The reputation of all preceding poets in Poland was now destined to be thrown into the shade by the appearance of Mickiewicz (1798-1855), the great introducer of romanticism into the country (see MICKIEWICZ). Poland, as has been said before, is not rich in national songs and legendary poetry, in which respect it cannot compare with its sister Slavonic countries Russia and Servia. Collections have appeared, however, by Wacław Zaleski, who writes under the pseudonyms of Wacław z Oleska, Wojcicki, Roger, Zegota Pauli, and especially Oskar Kolberg. Poland and Lithuania, however, abounded with superstitions and legends which only awaited the coming poet to put them into verse. In the year 1851 Romuald Zieliński published *Songs of the People of Piłsk*, and collections have even appeared of those of the Kashoubes, a remnant of the Poles living near Dantzic. Mickiewicz had had a predecessor, but of far less talent, Casimir Brodzinski (1791-1835). He served under Napoleon in the Polish legion, and has left a small collection of poems, the most important being the idyl *Wiesław*, in which the manners of the peasants of the district of Cracow are faithfully portrayed. The second great poet of the romantic school who appeared in Poland after Mickiewicz was Juliusz Słowacki (1809-1849), born at Krzemieniec. In 1831 he left his native country and chose Paris as his residence, where he died. His writings are full of the fire of youth, and show great beauty and elegance of expression. We can trace in them the influence of Byron and Victor Hugo. He is justly considered one of the greatest of the modern poets of Poland. His most celebrated pieces are *Hugo*; *Mnich* ("The Monk"); *Lambro*, a Greek corsair, quite in the style of Byron; *Anielli*, a very Dantesque poem expressing under the form of an allegory the sufferings of Poland; *Król Duch* ("The Spirit King"), another mysterious and allegorical poem; *Wacław*, on the same subject as the *Marya* of Malczewski, to be afterwards noticed; *Beniowski*, a long

poem in *ottava rima* on this strange adventurer, something in the style of Byron's humorous poems; *Kordyan*, of the same school as the English poet's *Manfred*; *Lilla Weneda*, a poem dealing with the early period of Slavonic history. The life of Słowacki has been published by Professor Anton Małeckie in two volumes.

Mickiewicz and Słowacki were both more or less mystics, but even more we may assign this characteristic to Sigismund Krasiński, who was born in 1812 at Paris, and died there in 1859. It would be impossible to analyse here his extraordinary poem *Nieboska Komedja* ("The Undivine Comedy"), *Irydion*, and others. In them Poland, veiled under different allegories, is always the central figure. They are powerful poems written with great vigour of language, but enveloped in clouds of mysticism. The life of Krasiński was embittered by the fact that he was the son of General Vincent Krasiński who had become unpopular among the Poles by his adherence to the Russian Government; the son wrote anonymously in consequence, and was therefore called "The Unknown Poet." Among his latest productions are his "Psalms of the Future" (*Psalmi Przyszłości*), which were attacked by the democratic party as a defence of aristocratic views which had already ruined Poland. His friend Słowacki answered them in some taunting verses, and this led to a quarrel between the poets. One of the most striking pieces of Krasiński has the title "Resurrecturis." The sorrows of his country and his own physical sufferings have communicated a melancholy tone to the writings of Krasiński, which read like a dirge, or as if the poet stood always by an open grave—and the grave is that of Poland. He must be considered as, next to Mickiewicz, the greatest poet of the country. Other poets of the romantic school of considerable merit were Gorecki, Witwicki, Odyńiec, and Gaszynski; the last-named wrote many exquisite sonnets, which ought alone to embalm his name. Witwicki (1800-1847) was son of a professor at Krzemieniec. He was a writer of ballads and poems dealing with rural life, which enjoyed great popularity among his countrymen and had the good fortune to be set to music by Chopin. The historical works of Lelewel have already had separate mention (see LELEWEL); but here may be specified the labours of Narbutt, *Dzieje Starożytne Narodu Litewskiego* ("Early History of the Lithuanian People"), published at Vilna in nine volumes, and the valuable *Monumenta Poloniae Historica*, edited at Lemberg by Bielowski, of which four volumes have appeared, containing reprints of most of the early chroniclers. Bielowski died in 1876.

A further development of romanticism was the so-called Ukraine school of poets, such as Malczewski, Goszczynski, and Zaleski. Anton Malczewski (1793-1826), who died at the early age of thirty-three, wrote one poem, *Marya*, which passed unnoticed at the time of its publication, but after its author's death became very popular. Malczewski led a wandering life and became intimate with Byron at Venice; he is said to have suggested to the latter the story of Mazeppa. *Marya* is a narrative in verse, written with much feeling and elegance, and in a most harmonious metre. The chief poem of Goszczynski is *Zamek Kaniowski* ("The Tower of Kaniow"). The most interesting poem of Bogdan Zaleski is his "Spirit of the Steppe" (*Duch od Stepu*). Other poets of the so-called Ukraine school, which has been so well inspired by the romantic legends of that part of Russia, are Thomas or Timko Padoura (who also wrote in the Malo-Russian, or Little-Russian, language), Alexander Groza, and Thomas Olizarowski. For many of the original songs and legends we must turn to the work of Messrs Antonovich and Dragomanoff. Bogdan Joseph Zaleski was born in 1802 in the Ukraine village, Boha-

terka. In 1820 he was sent to the university of Warsaw, where he had Goszczyński as a fellow-student. Since 1830 he has resided in Paris. Besides the longer poem previously mentioned, he is the author of many charming lyrics in the style of the Little-Russian poems, such as Sherchenko has written in that language. Michael Grabowski (1805-1863) belongs also to this school by his fine *Melodies of the Ukraine*. A poet of great vigour was Stephen Garczynski (1806-1833), the friend of Mickiewicz, celebrated for his *War Sonnets* and his poem entitled *The Deeds of Wacław*.

**Recent authors.** Among later authors, some of whom still survive, may be mentioned Wincenty Pol, born in 1807 at Lublin. He wrote a fine descriptive work, *Głazy i Pola* ("Pictures of Life and Travel"), and also a poem, *Pieśń o Ziemi Naszej* ("Song of our Land"). For about three years from 1849 he was professor of geography in the university of Cracow. In 1853 he published *Mohort*, a poem relating to the times of Stanislaus Poniatowski. Ludwik Władysław Kondratowicz (who wrote chiefly under the name of Syrokomla) was born in 1823 in the government of Minsk. His parents were poor, and he received a meagre education, but made up for it by careful self-culture. One of his most remarkable poems is his *Jan Długosz*, in which, like Mickiewicz, he has well described the scenery of his native Lithuania. He everywhere appears as the advocate of the suffering peasants, and has consecrated to them many beautiful lyrics. In Kaczkowski the Poles have a novelist who has treated many periods of their history with great success. His sympathies, however, are mostly aristocratic, though modified by the desire of progress. An important writer of history is Karl Szajnoch, born in Galicia of Czech parents in 1815. He began his labours with *The Age of Casimir the Great* (1845), and *Polonia the Brave* (1849), following these with *Jadwiga and Jagiello*, in three volumes (1855-1858),—a work which Spasowicz, in his *Russian History of Slavonic Literature*, compares in vigour of style and fulness of colour with Macaulay's *History of England* and Thierry's *Norman Conquest*. Our author was still further to resemble the latter writer in a great misfortune; from overwork he lost his sight in 1857. Szajnoch, however, like Thierry and the American Prescott, did not abandon his studies. His excellent memory helped him in his affliction. In 1853 he published a work in which he traced the origin of Poland from the Varangians (*Lechicki początek Polski*), thus making them identical in origin with the Russians. He began to write the history of John Sobieski, but did not live to finish it, dying in 1863, soon after completing a history of the Cossack wars, *Dwa lata dziejów naszych* ("Two Years of Our History"). A writer of romances of considerable power was Joseph Korzeniowski, tutor in early youth to the poet Krasiński, and afterwards director of a school at Kharkoff. Besides some plays now forgotten, he was author of some popular novels, such as *Wielki oryginalista* ("Tours of an Original"), 1843; *Gurłat* ("The Hunchback"), 1852, &c. He died at Dresden in 1863. But the most fertile of Polish authors beyond all question is Krasiński (born in 1812). His works constitute a library in themselves; they are chiefly historical novels, some of which treat of early times in Poland and some of its condition under the Saxon kings. Up to 1879, when he celebrated the fiftieth anniversary of his commencing authorship, he had written two hundred and fifty separate works in four hundred and forty volumes. One of the most popular of his novels is *Jermol the Potter*, a pathetic and noble story, which much resembles George Eliot's *Silas Marner*, but appeared in 1857, some time before the publication of that work. A charge of treason was recently brought against Krasiński by the German Government, and he is now (1885) undergoing a sentence of imprisonment at Magdeburg. Among the various works of Krasiński may be mentioned an interesting one on Lithuania (*Litwa*), which contains many valuable accounts of Lithuanian customs; perhaps, however, the historical and philological parts of the work are not always very critically treated. He is the author of two volumes of poetry. As lyrical poets may also be mentioned Jachowicz, Jałkowski, author of a fine poem *The Beginning of Winter*, Wasilewski, and Holowinski, archbishop of Moghileff (1807-1855), author of religious poems. The style of poetry in vogue in the Polish parts of Europe at the present time is chiefly lyrical. Other writers deserving mention are Cornelius Ujejski (born in 1823), the poet of the last revolt of 1863; Theophilus Lenartowicz (born 1822), who has written some very graceful poetry; Sigismund Milkowski (born in 1820), author of romances drawn from Polish history, for the novel of the school of Sir Walter Scott still flourishes vigorously among the Poles. Among the very numerous writers of romances may be mentioned Henry Rzewuski (1791-1866); Joseph Dzierzkowski wrote novels on aristocratic life, and Michael Czajkowski tales of adventure; Valerius Wicłogowski (1865) gave pictures of country life. Of course at the head of all writers in this department must be considered the unfortunate Krasiński.

In 1852 the Poles lost, in the prime of life, a very promising historian Szujski (born in 1835), and also Schmitt, who died in his sixty-sixth year. Szujski commenced his literary career in 1859 with poems and dramas; in 1860 appeared his first historical production, *Rzut oka na Historię Polski* ("A Glance at Polish History"), which attracted universal attention; and in 1862 he commenced the publication in parts of his work *Dzieje Polski* ("The History of Poland") the printing of which ceased in 1866. The value of this book is great both on account of the research it displays and its philosophical and unprejudiced style. One of the last works of Szujski, written in German, *Die Polen und Ruthenen in Galizien*, attracted a great deal of attention at the time of its appearance. Schmitt got mixed up with some of the political questions of the day—he was a native of Galicia and therefore a subject of the Austrian emperor—and was sentenced to death in 1846, but the penalty was commuted into imprisonment in Spielberg, whence he was released by the revolution of 1848. In 1863 he took part in the Polish rebellion, and was compelled to fly to Paris, whence he only returned in 1871. His chief works are *History of the Polish People from the Earliest Times to the year 1763* (1854), *History of Poland in the 18th and 19th Centuries* (1866), and *History of Poland from the time of the Partition* (1868), which he carried down to the year 1832. In opposition to the opinion of many historians, his contemporaries, that Poland fell through the nobility and the diets, Schmitt held (as did Lelewel) that the country was brought to ruin by the kings, who always preferred dynastic interests to those of the country, and by the pernicious influence to the Jesuits. Adalbert Kętrzyński, who succeeded Bielowski in 1877 in his post of director of the Ossolinski Institute at Lemberg, is the author of some valuable monographs on the history of Poland. He was born in 1838. Kasimir Stadnicki has treated of the period of the Jagiellons; and Szaraniewicz, professor at the university of Lemberg, has written on the early history of Galicia. Thaddeus Wojciechowski has published a clever work on Slavonic antiquities. Xavier Liske, born in 1838, and now professor of universal history at Lemberg, has published many historical essays of considerable value, and must be a linguist of great attainments, as separate works by him have appeared in the German, Polish, Swedish, Danish, and Spanish languages. The "Sketch of the History of Poland" (*Dzieje Polskie w Zarysie*) by Michael Bobrzyński, born in 1849 in Cracow (where he is professor of Polish and German law), is a very spirited work, and has given rise to a great deal of controversy on account of the opposition of many of its views to those of the school of Lelewel. Vincent Zakrzewski, now professor of history at Cracow, has written some works which have attracted considerable attention, such as *On the Origin and Growth of the Reformation in Poland*, and *After the Flight of King Henry*, in which he describes the condition of the country during the period between that king's departure from Poland and the election of Stephen Batory. Smolka has published a history entitled *Mieszko the Elder and his Age*. Władysław Wistocki has prepared a catalogue of manuscripts in the Jagiellon library at Cracow. Dr Joseph Casimir Plebański is now editor of the *Biblioteka Warszawska*, a very valuable literary journal which stands at the head of all works of the kind in Poland. He has also written a dissertation (in Latin) on the *liberum veto*, which puts that institution in a new light. Felix Jezierski, the previous editor of the above-mentioned journal, published in it translations of parts of Homer, and is also the author of an excellent version of *Faust*.

The history of Polish literature has not been neglected. We first have the early history of Felix Bentkowski (1761-1852), followed by that of Michael Wiszniewski (1794-1865), which, however, only extends to the 17th century, and is at best but a quarry of materials for subsequent writers, the style being very heavy. A "History of Eloquence" (*Historia Wypowiedzi w Polsce*) was published by Karl Mecherzynski. An elaborate history of Polish literature is now in course of preparation by Anton Matecki, who is the author of the best Polish grammar (*Gramatyka Historyczno-Porównawcza Języka Polskiego*, 2 vols., Lemberg, 1879). The Polish bibliography of Karl Estricher, now director of the Jagiellon library at Cracow, is a work of the highest importance. One of the most active writers on Polish philology and literature is Władysław Nehring, whose numerous contributions to the *Archiv für Slavische Philologie* of Professor Jagie entitle him to the gratitude of all who have devoted themselves to Slavonic studies. Władimir Spasowicz, a lawyer of St Petersburg, has assisted Pipin in his valuable work on Slavonic literature. The lectures of Professor Cybulski (ob. 1867) on Polish literature in the first half of the 19th century are written with much spirit and appreciation. The larger poetical works which appear during that time are carefully analysed.

In recent times many interesting geological and anthropological investigations have been carried on in Poland. In 1863 Count Constantine Tyszkiewicz published a valuable monograph on the *Tombs of Lithuania and Western Ruthenia*. A diligent searcher for antiquities is Prof. Joseph Łepkowski of Cracow, who has greatly enriched the archaeological museum of his native city.

Lisbon was erected into a patriarchate, and the title of "Fidelissimus" or "Most-Faithful" was conferred upon the kings of Portugal, to correspond with those of "Most Christian" and "Most Catholic" attributed to the kings of France and Spain respectively.

Joseph. Joseph, who succeeded his father in 1750, had the merit of perceiving the pre-eminent powers of Sebastião de Carvalho, who governed Portugal throughout this reign, and who, under his title of the marquis of Pombal (see POMBAL), ranks among the very greatest of 18th-century statesmen. In everything—in his great internal and administrative reforms, in his financial reforms, in the reorganization of the army, in the abolition of slavery, and in the great struggle with the Jesuits—Joseph supported his minister. Pombal made the king more absolute than ever, and exalted the royal prerogative while using it for purposes of reform; and in return the king maintained Pombal in power in spite of the violent protests of the priests and the opposition of his wife. Circumstances greatly helped the minister to establish an ascendancy over the king's mind: his conduct at the time of the great earthquake on 1st November 1755 secured him his high position over the other two secretaries of state; the Tavora plot gave him the influence which enabled him to overthrow the Jesuits in 1759; and the second attempt on the king's life in 1769 strengthened his hands in his negotiations with Rome and ensured the suppression of the order in 1773. The only war in which Portugal was engaged during this reign was caused by the close alliance with England, for, when Choiseul made the Family Compact and Spain entered upon the Seven Years' War, a Spanish army under the marquis of Sarria invaded Portugal and took Braganza and Almeida in 1762. Pombal immediately applied to England for help, when the count of Lippe-Bückeburg came over with a body of English troops and set to work to organize the Portuguese army; and, mainly owing to the brilliant services of Brigadier-General Burgoyne, the Spaniards were defeated at Valencia de Alcántara and Villa Velha, and peace was made on 10th February 1763. The close of the reign was disturbed by disputes with Spain as to the possession of Sacramento in South America, which were still unsettled when King Joseph died on 20th February 1777, leaving four daughters, of whom the eldest, Donna Maria Francisca, had married the king's brother, Dom Pedro.

Maria I. and Pedro III. The accession of Donna Maria was the signal for the overthrow of the great marquis and the reversal of his policy. The new queen was a weak woman, and her husband, Dom Pedro, who was proclaimed king, was a weak man; coins were struck in the names of Pedro III. and Maria I., but both sovereigns were ruled by the queen-dowager, who hated Pombal, and eventually sentenced him never to come within twenty leagues of the court. The incapacity of his successor soon became manifest, while the queen, who was completely under the sway of her confessor, Dom Ignacio de San Caetano, found her greatest happiness in raising and sending large sums of money to the Latin convent at Jerusalem. Such was the state of Portugal when the great crisis in the world's history caused by the French Revolution was at hand; and, when in 1792 it became evident that affairs could no longer go on in this haphazard fashion, it was also evident that the queen was no longer fit even for the slight fatigue she had to undergo. Her brain had given way in 1788, after the successive deaths of her husband, of her eldest son Dom Joseph, who had married his aunt, Donna Maria Benedicta, and of her confessor, and Dom John found it necessary to take the management of affairs into his own hands, though he was not actually declared regent until 1799.

About the time that Dom John became regent the wish to check the spread of the principles of the French Revolution, which were as much feared in Portugal as in all other Continental states, led to the great activity of Dom Diogo Ignacio de Pina Manique, the intendant-general of police. He eagerly hunted down all Portuguese gentlemen suspected of encouraging French principles or of being freemasons, expelled all Frenchmen from the kingdom, and kept a jealous eye on the American consul, Edward Church, and a merchant named Jacome Ratton, whom he declared to be at the head of a republican conspiracy. Moreover, the Portuguese ministers not only combated the dreaded French principles at home, they also believed it a holy duty to join in the general war against France, and therefore a corps of 5000 men was sent into the eastern Pyrenees to serve under General John Forbes Skelater, and four ships under the marquis of Niza joined the English fleet in the Mediterranean. The Portuguese force under Forbes Skelater served in all the actions in the eastern Pyrenees, in the successes of General Ricardos, and in the defeats of the count de la Union and General Urrutia; but nevertheless the Spanish Government, then under the influence of Godoy, the Prince of the Peace, did not hesitate to desert Portugal and make a separate peace with the French republic at Basel in July 1795. This naturally drove Portugal into a still closer alliance with England; and, when, after the treaty of San Ildefonso (1796), by which Spain declared war against England, and the secret convention between Pérignon and Godoy to divide Portugal between them, Spanish troops were massed on the Portuguese frontiers, an urgent supplication for help was sent to England. In response the House of Commons voted Portugal a subsidy of £200,000; a force of 6000 men was despatched under Major-General Sir Charles Stuart, which deterred the Spaniards from attempting an invasion; and the prince of Waldeck, like the count of Lippe in former days, was sent to reorganize the Portuguese army. Yet the English party was not strong enough to carry the day entirely; Sir Charles Stuart was soon withdrawn, and an effort made to secure peace with France through the mediation of Spain. But the concessions of the French party were of no avail; the First Consul was as violently opposed to Portugal, as being a province of England, as the Convention and Directory had been, and in 1800 Lucien Bonaparte was sent to Madrid with instructions from his brother to insist on the abandonment of the English alliance, on the opening of Portuguese ports to France and the closing of them to England, on the extension of French Guiana to the Amazons, on the cession of a portion of Portugal to Spain, until the recovery from England of Trinidad, Port Mahon, and Malta, and on the payment of a large sum of money, and he was authorized to offer to Spain a corps of 15,000 Frenchmen if these hard terms were rejected. The Portuguese ministers did reject them, and immediately Leclerc's corps entered Spain. The campaign lasted but a few days. Olivenza and Campo Mayor fell into the hands of the Spaniards, who also won bloodless victories at Arronches and Flor da Rosa. Peace was made at Badajoz with Spain, by which Portugal ceded Olivenza, and at Paris with France, by which it consented to the extension of French Guiana to the Amazons, and promised a large indemnity. Napoleon Bonaparte was anything but satisfied with the treaty of Badajoz, and received Lucien on his return with but little favour, for his aim was utterly to destroy Portugal as a nation; and it was with a full intention to excite her to war that he sent one of the roughest and least educated of his generals, Lannes, as ambassador to Lisbon. Lannes acted fully up to his chief's expectations: he ordered the dismissal of all the ministers who favoured England, and

The Pen-  
insular  
War.

was obeyed both from fear of France and from a dislike of England owing to her high-handed naval policy. Even this humble submission of the regent did not satisfy Napoleon, and in 1804 he replaced Lannes by Junot, whom he ordered to insist upon Portugal's declaring war against England. Then for a time he desisted from executing his plans against the country owing to his great campaigns in Europe, and made a treaty of neutrality with the Portuguese Government. At length in 1807, having beaten Austria, Prussia, and Russia, Napoleon again turned his thoughts to his project for the annihilation of Portugal, which had become more than ever a thorn in his side, since it refused to co-operate in his Continental schemes for ruining England. He resolved at first to act with Spain and Godoy, as Pérignon had done in 1797, and on 29th October 1807 signed the treaty of Fontainebleau, by which it was arranged that Portugal should be conquered and divided into three parts: the northern portion should be given to the king of Etruria in the place of his Italian kingdom, which Napoleon desired to annex, while the southern portion was to be formed into an independent kingdom for Godoy, and the central provinces were to be held by France until a general peace. The signature of the treaty was followed by immediate action: Junot moved with an army rapidly across Spain, and, together with a Spanish force under General Caraña, entered Portugal from the centre, while General Taranco and General Solano with two other Spanish armies occupied the Minho and Alemtejo. With amazing rapidity Junot accomplished the march, and the Portuguese hardly knew that war was imminent until on 27th November Colonel Lecor rushed into Lisbon with the news that the French were in possession of Abrantes. This alarming intelligence unnerved the regent, who listened to the strongly-worded advice of Sir Sidney Smith, commander of the English ships in the Tagus, to abandon his kingdom for the Brazils, and leave the English to defend Portugal; and on 27th November Dom John, after naming a council of regency, went on board the English fleet with his whole family, including the queen Maria I. The English ships had hardly left the Tagus when a small force of wearied French soldiers, who were all that remained from the terrible fatigues of the march, entered Lisbon on 30th November.

Nothing proves more certainly the widely-spread existence of what were called French principles—that is to say, democratic ideas—in Portugal than the hearty reception which Junot met with from the first. At Santarem a deputation of the freemasons of Portugal, who were there, as in other Continental countries, a secret society for the propagation of democratic principles, welcomed him; the marquis of Alorna with the army instantly submitted to him; and the council of regency, knowing the temper of the citizens, made no attempt to hold Lisbon against him. But Junot showed no desire to grant the Portuguese a constitution, and after seizing all the money in the royal treasury he divided the country into military governments under his generals, issuing on 1st February a proclamation that the house of Braganza had ceased to reign. He then began to hope that he himself might succeed the Braganzas, and for this purpose sought to conciliate the Portuguese by reducing the requisition demanded by Napoleon from forty millions of francs to twenty millions, and commenced a negotiation with the radical or French party in Portugal through Luca de Scabra da Silva to induce them to send a petition or deputation to the emperor, asking for Junot to be their king. But his attempts at conciliation were of no avail; and, when the Spanish general Bellesta, who had succeeded Taranco at Oporto, seized the French governor, General Quesnel, declared for the regent, and marched into Galicia, Junot departed from Lisbon, leaving

the city in the hands of a regency, headed by the bishop of Oporto. The bishop at once sent to England for help, and encouraged fresh revolts all over the kingdom, till nearly every city in Portugal rose against the French and established its own junta of government. Meanwhile the English Government had willingly listened to the request of the bishop of Oporto, and ordered the small army which had been collected at Cork, under the command of Lieutenant-General Sir Arthur Wellesley, for an expedition to South America, to proceed to Portugal. Sir Arthur landed at the mouth of the Mondego river, advanced towards Lisbon, and, after defeating Laborde's division at Roliça on 17th August 1808, routed Junot himself at Vimieiro on 21st August. These victories were followed by the convention of Cintra, by which Junot agreed to vacate Portugal and give up all the fortresses in his possession; this convention, however disappointing from a military point of view, was eminently satisfactory to the Portuguese people, who saw themselves as speedily delivered from the French as they had been conquered by them. The regency was again established, and at once despatched Domingos Antonio de Sousa Coutinho, a brother of the count of Linhares, to London, to ask that an English minister with full powers should be sent to Lisbon, and that Sir Arthur Wellesley might be appointed to reorganize their army. Their requests were complied with: the Right Honourable J. C. Villiers was sent to Lisbon, and, as Sir Arthur Wellesley could not be spared, Major-General Beresford, who had learned Portuguese when governor of Madeira, which he had occupied in the preceding year, was sent to command their army. Portugal, however, was not yet safe from the French; Sir John Moore's advance to Salamanca and his retreat to Corunna had left the country but slightly garrisoned, and, in spite of the braggadocio of the bishop, Oporto quickly fell into the hands of Marshal Soult. Fortunately Soult, like Junot, was led away by the idea of becoming king of Portugal, and did not advance on Lisbon, thus giving time for Sir Arthur Wellesley again to arrive in the country with a powerful army. In the interval the Portuguese, in spite of some spirited fights by General Silveira, had shown how little they could do in their disorganized state, and the English Government determined to send out English officers to organize them and to take 10,000 Portuguese into English pay. Meanwhile Sir Arthur Wellesley had driven Soult from Oporto, had advanced into Spain, and won the battle of Talavera. From these successes of the English general it is pitiable to turn to the Portuguese regency. With the departure of the king all the able men of the royal party seemed to have left the country; the leaders of the radical party were either in disgrace or had fled to France; and none were left to compose the regency save a set of intriguers, whose chief idea was to get as much money from England as possible. The best part of the nation had entered the army, hence Marshal Beresford, aided by the adjutant-general Manuel de Brito Mousinho, soon organized a force which at Busaco proved itself worthy to fight beside the English soldiery. The regency got from bad to worse, till neither Beresford nor Wellington could work with it, and the English cabinet had to demand that Sir Charles Stuart (son of General Sir Charles Stuart), their ambassador at Lisbon, should receive a place upon it. His great ability and tact soon made him master, and a certain portion of the money sent by England to pay the Portuguese troops did then find its way to its proper destination. Yet the regency, even when thus strengthened, failed to make itself popular; and that there was a large radical party in Lisbon is sufficiently proved by the deportation of eighteen journalists to the Azores in September 1810. The troubles of Portugal were not yet over; the most formidable invasion

of all was to come. During the time of Masséna's campaign in Portugal the Portuguese showed the valour of a truly heroic nation. When Lord Wellington determined to retire to the lines of Torres Vedras, he commanded all the peasants to desert their fields and leave nothing for the French to subsist upon, and they obeyed him with touching fidelity. The Portuguese troops fully proved their value as soldiers when led and trained by such English generals as Pack and Ashworth, Bradford and John Hamilton, on every battlefield in the Peninsula and the south of France, and especially at Salamanca and the Nivelle. They well deserved the praise bestowed upon them by Wellington and Beresford, and the enthusiastic reception which they met with when they returned home in 1814.

VI. Shortly after the conclusion of the war, in 1816, the mad queen Maria I. died, and the regent succeeded to the throne as King John VI. The English Government earnestly pressed him to return to Lisbon, where dissensions in the regency and the universal discontent urgently summoned him. But the new king was perpetually hampered by his intriguing and ambitious wife, Carlota Joaquina, who, in order to raise a party in her favour, had as early as 1805 promised a constitution to the Portuguese, and in 1812 had plotted to become independent queen of Brazil. The regency had become intensely unpopular, for Sir Charles Stuart and Marshal Beresford ruled despotically; and the mass of the people, who had been willing to endure the despotism of the English during the terrible war for existence, as well as the army, which had willingly obeyed the English officers on the field of battle, grew weary of foreign rule in time of peace and raised the cry of Portugal for the Portuguese. Directly after the war, in 1817, the first rising took place in Lisbon in the form of a pronunciamiento of General Gomes Freire de Andrade, who had commanded the Portuguese contingent in the Russian campaign of 1812; but it was instantly and cruelly suppressed by Beresford and the regency, and the general and eleven others were executed. Yet the radical party was by no means conquered, and when Beresford went to Rio de Janeiro in 1820 advantage was taken of his absence by the people of Oporto, headed by certain officers in the garrison, to raise the cry for reform; the regency, unable to act without Beresford, gave way before a similar rising at Lisbon; the English officers were everywhere expelled; a new regency was proclaimed; Beresford was not allowed to land when he returned from Brazil; and a constituent assembly was summoned. The new assembly, consisting largely of men of the most radical opinions, at once abolished the Inquisition and the relics of feudalism, and proceeded to draw up an impracticable constitution, which showed that they had studied the glowing speeches of the men of the French Revolution and had not profited by a knowledge of their mistakes. Prussia, Austria, and Russia withdrew their ambassadors, and England insisted on John's returning to his kingdom. He accordingly left the Brazils to the government of his elder son Pedro, and set out for Portugal, where in 1822, at the earnest request of that son, he solemnly swore to obey the new constitution. He was at once met by the opposition of the queen and his younger son Dom Miguel, who refused to recognize the constitution; in consequence they were expelled from Lisbon. This event, with the invasion of Spain by the French to put down the rebellion of 1823, encouraged Francisco da Silveira, count of Amarante, to raise a pronunciamiento in Tras-os-Montes; but the king at Lisbon declared, amid loud applause, that the constitution of 1822 was abrogated and his own absolutism restored, and he appointed the count of Palmella, the head of the English or constitutional party, to be his minister. But the absolutist party did not aim at a new form of constitutional

government; they were desirous to reinstate the old absolutism. The queen and Dom Miguel headed a new plot; the king's friend, the marquis of Loulé, was assassinated; Palmella was imprisoned and the king himself shut up in his palace. The united action of the foreign ministers who had remained in Lisbon freed the king; the new insurrection was suppressed; Palmella was again appointed minister; and the king, with the two chief conspirators, the queen and Dom Miguel, left Portugal once more for the Brazils. In the following year (1826) John VI. died, leaving by his will his daughter, the infanta Isabel Maria, as regent, to the great disappointment of Dom Miguel, who had returned to Portugal with the expectation of receiving it as his inheritance, while his brother Dom Pedro ruled in Brazil.

The next twenty-five years are the darkest in the whole history of Portugal and the most complicated to analyse, for the establishment of parliamentary government was no easy task; it is almost impossible to follow the rapid changes which succeeded each other, and quite impossible to understand the varying motives of the different statesmen and generals. The keynote to the whole series of the disturbances is to be found in the influence of the army. Beresford's creation was a grand fighting machine; but armies, and more particularly generals, are almost certain to intrigue in times of peace. On ascending the united thrones Dom Pedro IV. proceeded to draw up a charter containing the bases of a moderate parliamentary government and sent it over to Portugal by the English minister, Sir Charles Stuart, and then abdicated the crown of Portugal in favour of his daughter, Donna Maria da Gloria, a child only seven years old, on condition that she married his brother Dom Miguel, who was to recognize the new constitution. The charter was received with joy by the parliamentary party, and Palmella became prime minister; but in 1827 the king foolishly appointed Dom Miguel to be regent in Portugal. This ambitious prince was exceedingly popular with the old nobility, the army, and the poor; and, having declared himself absolute king, he drove the whole constitutional or chartist party—Palmella, Saldanha, Villa Flor, Sampaio, and their adherents—into exile. They fled to England, where the young queen then was, but, although they found popular opinion strongly in their favour, they found also that the duke of Wellington and his Tory ministry highly approved of Dom Miguel's behaviour, and that they persisted in confounding the moderate and the radical parties, and in believing that Palmella was a democrat. Meanwhile the reign of Dom Miguel had become a reign of terror, and a new movement was begun by the conjoined chartist and radical parties, who respectively advocated the charter of 1826 and the constitution of 1822, but who sank their differences to oppose Dom Miguel. The island of Terceira (Azores) had never submitted to this prince, and there in 1829 the marquis of Palmella, the count of Villa Flor, and José Antonio Guerreiro declared themselves regents for the young queen; and on 11th August 1830 they defeated in Praia Bay the fleet sent against them by Dom Miguel. This victory was the first ray of hope to the chartist party; all who could get away from Portugal hastened to the Azores; and in 1831 Dom Pedro, having resigned the imperial crown of Brazil to his infant son, came to London to join his daughter and prepare for a vigorous struggle against his brother. He met with acquiescence, if not encouragement, from the Liberal Government of Earl Grey, and managed to raise a large loan; then he betook himself with all the troops he could raise to the Azores, where he appointed the count of Villa Flor general-in-chief and Captain Sartorius of the English navy commander of the fleet. In July 1832 Dom Pedro arrived at Oporto with 7500 men, being enthusiastically welcomed

by the citizens; Dom Miguel instantly laid siege to the city. The siege was a terrible one; want within the walls and cholera among the besiegers decimated the armies, and the only real success gained was the victory of Sartorius over the fleet of Dom Miguel on 11th October. In 1833 more vigorous action began; Major-General João Carlos Saldanha de Oliveira e Daun, count of Saldanha, an old officer of Beresford's and a member of the Palmella Government in 1825, took the command in Oporto and beat off the French general Bourmont, who had been engaged by Dom Miguel to command his forces; the count of Villa Flor sailed from Oporto to Algarves, defeated General Telles Jordão, and after a triumphal march northwards occupied Lisbon; and Captain Charles Napier, who had succeeded Sartorius, destroyed Dom Miguel's fleet off Cape St Vincent in 1833. In this year Queen Maria came to Lisbon and was received with transports of delight, while Dom Pedro as regent again proclaimed the charter of 1826. The year 1834 was one of unbroken success for the chartists; England and France recognized the queen, and the Spanish ministry of Queen Isabella, knowing Dom Miguel to be a Carlist, sent two corps under Generals Rodil and Serrano to the help of Dom Pedro. Saldanha defeated the forces of the usurper at Torres Novas and Alamoater; Napier reduced Beira; Villa Flor, who had been made duke of Terceira, reduced Trás-os-Montes and won a victory at Aveicira; Sá de Bandeira reduced Alentejo; the combined Spanish and Portuguese armies surrounded the rest of Dom Miguel's adherents at Évora Monte; and Dom Miguel himself capitulated on 26th May. By the convention of Évora Monte the usurper, on condition of receiving a pension, promised to leave Portugal for ever; and the cortes at Lisbon not only declared him and his heirs ineligible for the throne but forbade them to return to Portugal under penalty of death. This same cortes attempted to arrange the finances, and abolished the orders of the friars, who had hitherto kept alive the party of rebellion in the villages, and finally, at Dom Pedro's request—for he felt his health failing—declared the queen of age on 18th September 1834. Dom Pedro, who had throughout been the heart and soul of his daughter's party, retired to Queluz (near Lisbon), where he died six days afterwards from the effects of his great labours and fatigues.

**Maria II.** The death of Dom Pedro deprived Queen Maria II., who was now only fifteen, of her greatest support, but a very strong ministry was formed, with the duke of Palmella as president and the duke of Terceira at the war office. Such a ministry might have lasted for a long time, but neither the queen, the nobility, nor the people understood the principles of real constitutional government, and the army was a constant source of danger. Members of different parties, while not conceiving that all alike loved Portugal, believed sincerely in their own opinions: the party in power proscribed and exiled its opponents, while the party in opposition invariably appealed to arms instead of seeking to obtain office by legitimate parliamentary means. In addition, the country was ravaged by bands of brigands, who called themselves "Miguelites," and who perpetually escaped into Spain when attacked in force; and, as each Government refused to recognize or pay interest upon the loans raised by its predecessors, the financial credit of Portugal soon fell to a very low ebb in the money markets of Europe. It is unprofitable to examine here the principles of the chief statesmen of the time as new Governments quickly succeeded each other; it will be sufficient to notice only the chief pronunciamentos and appeals to arms, and to remark the gradual approach to real parliamentary government. Queen Maria da Glória's reign is one of violent party struggles, for they can hardly be called civil wars, so little did they involve, and that of

King Luis the reign of definite and peaceable parliamentary government. In her earlier years the queen was chiefly under the influence of her stepmother, the second wife of Dom Pedro, Amelia of Bavaria, and in 1835 she married the queen-dowager's brother, Augustus Charles Eugène Napoleon, duke of Leuchtenberg, second son of Eugène Beauharnais by the princess Augusta of Bavaria, who died two months after his marriage, in March 1835. In the following January Maria married Prince Ferdinand of Saxe-Coburg-Gotha, nephew of Leopold, the first king of the Belgians; and it was his nomination to the post of commander-in-chief that brought about the first appeal to arms. In September 1836 Fernando Soares da Caldeira headed a pronunciamento in Lisbon for the re-establishment of the constitution of 1822, which was completely successful, and resulted in the drawing up of a new constitution. The constitution of 1838, which was really that of 1822 slightly modified, managed to work till 1842, when one of the radical ministers, Antonio Bermudo de Costa Cabral, suddenly declared the charter of 1826 at Oporto. The duke of Terceira headed a successful pronunciamento in favour of the charter, and came into office with Costa Cabral as home secretary and virtual prime minister. Costa Cabral, who in 1845 was created count of Thomar, made himself very acceptable to the queen, and, interpreting the charter in the most royalist sense, even attempted to check the freedom of the press. It was now the turn of the radicals or Septembrists to have recourse to arms: after an attempt to place Saldanha in office, the opposition broke out into open insurrection under the viscount of Sá de Bandeira, the count of Bomfim, and the count das Antas. This new insurrection is known as the War of Maria da Fonte or "patuleia," and was not suppressed until the conclusion of the convention of Granada on 29th June 1847, when a general amnesty was declared, Saldanha being continued in power. Queen Maria da Glória died on 15th November 1853, and her husband, the king-consort, Dom Ferdinand II., assumed the regency until his eldest son Dom Pedro V. came of age.

The era of peaceful parliamentary government which succeeded the stormy reign of Queen Maria II. has been one of prosperity for Portugal, and much of that peace and prosperity is due to the great literary and historical revival which is signalized by the names of João Baptista de Almeida Garrett and Antonio Feliciano de Castilho, of Alexandre Herculano de Carvalho e Araújo and Luís Augusto Rebello da Silva. Men were not wanting in the early part of the 19th century to advocate the formation of an Iberian republic or kingdom, comprising the whole of the Peninsula; but the revival of national pride in recalling the glorious past of Portuguese history, which has been the work alike of Herculano and Almeida Garrett in different lines, has breathed afresh the spirit of patriotism into a people who had been almost wearied out by continual pronunciamentos. The only political event of any importance during the reign of Dom Pedro V., who came of age Pedro V. and assumed the government in 1855, and who in 1857 married the princess Stephanie of Hohenzollern, was the affair of the "Charles et Georges." This French ship was engaged in what was undoubtedly the slave-trade, though slightly disguised, off the coast of Africa, when it was seized by the authorities of Mozambique, and, in accordance with the laws and treaties against the slave-trade, its captain, Roussel, was condemned to two years' imprisonment. The emperor Napoleon III., glad to have a chance of posing before the French people, and counting on his close alliance with England, instantly sent a large fleet to the Tagus under Admiral Lavaud, and demanded compensation, which, as England showed no signs of assistance, Portugal was compelled to pay. The whole country, especi-

ally the city of Lisbon, was ravaged by cholera and yellow fever during this reign, itself evidence of the extreme neglect of all sanitary precautions; and on 11th November 1861 the king, who refused to quit the pestilence-stricken capital, died of cholera, and was speedily followed to the grave by two of his brothers, Dom Ferdinand and Dom John.

At the time of Dom Pedro's death his brother and heir, Dom Luis, was travelling on the Continent; and his father, Dom Ferdinand, again assumed the regency until his son's return, soon after which Luis married Maria Pia of Savoy, daughter of Victor Emmanuel, king of Italy. The new king followed his brother's policy and allowed his ministers to fight their battles in the chambers without interference from himself. During his reign the old combatants of the reign of Maria da Gloria died off one by one,—Palmella, Terceira, Thomar, Saldanha, and Sá de Bandeira. Their successors in political leadership, the duke of Loulé, Aguiar, the marquis of Avila, and Antonio Manuel Fontes Pereira de Mello, though not inferior in administrative ability, always avoided an appeal to arms, and therefore, if they do not contribute striking pages to the history of Portugal, certainly contributed more to the prosperity of the country. The last pronunciamiento, or rather attempt at a pronunciamiento, of the last survivor of Queen Maria's turbulent statesmen, the duke of Saldanha, in 1870, only proved how entirely the day of pronunciamientos had gone by. He conceived the notion that the duke of Loulé, as a freemason and an advanced progressist, was a favourite with the king, after the manner of the duke of Polignac and Charles X. of France; so, recalling a few such historical examples to the king's mind, he insisted on the duke's dismissal, and threatened an appeal to arms. The king, perceiving that Saldanha was in earnest, and knowing the great influence of the old man, consented to dismiss the duke of Loulé. After keeping Saldanha himself in office for four months, Luis sent him as ambassador to London notwithstanding his eighty years, where he could do no mischief, and where he died in 1876. The steady prosperity of Portugal has been largely due to the present form of government based on the charter of 1826, as modified in 1852, and is borne witness to by the reconstitution of the House of Peers in 1878 from an hereditary assembly to one of life peers. It is a notable fact that the two loans raised by the Portuguese Government in 1880 and in 1882 were quickly subscribed, and mainly within Portugal itself. Of recent years much attention has been drawn to the Portuguese settlements in Africa, since the opening up of the interior has made them of vast importance on both the east and the west coast. The king, ministers, and people of Portugal are fully aware of the new vista to their prosperity thus disclosed to them, and the Portuguese travellers Serpa Pinto, Roberto Ivens, and Brito Capello have taken an important share in the explorations which have opened up the interior of Africa and paved the way for its development. Public works, however, have not been neglected, and Fontes Pereira de Mello, the leader of the "regenerator" party, who has been prime minister three times—from 1871 to 1877, from 1878 to 1882, and from 1883—has steadily improved and extended the railway and telegraph systems, and carried out the more difficult labours of sanitary reform. Education also has not been neglected, and a good system of secondary and primary education has been established, mainly owing to the labours of the Portuguese poet, Antonio Feliciano de Castilho. The share taken by the leaders of the great literary and historical revival—which dates from the conclusion of the civil wars of 1846 and the publication of the first volume of Herculano's *History of Portugal* in 1848—in Portuguese political and social reform is a marked feature of the modern parlia-

mentary life of the country; and not only have the poets Almeida Garrett and Mendes Leal and the historian Rebello da Silva held office, but many of the most promising of the new generation of literary men, such as Latino Coelho and Pinheiro Chagas, have distinguished themselves in politics. Few countries so well realize the advantages of a constitutional and parliamentary form of government as Portugal; socialism possesses there a reforming, not a revolutionary force; unity of pride in their country inspired by great writers has made the modern Portuguese ambitious to revive the glories of the past, and united men of all shades of opinion in a common patriotism. The Camoens celebration of 1880 showed that the Brazilians were still proud of their mother-country, and that the Portuguese race all over the world was ready to develop new energy and perseverance, and to prove its true descent from the men who under Affonso Henriques overthrew the Moors, who under John I. and John IV. rejected the rule of the Spaniards, under Affonso de Albuquerque and João de Castro conquered the East, and who by the voyage of Vasco de Gama created a new era in the history of the world.

*Bibliography.*—The best continuous history of Portugal is still that of Heinrich Schaefer, in Heeren and Ukert's *Europäische Staats-Geschichte*, 1840-46, partly translated into Portuguese by J. L. Domingues de Mendonça (Lisbon, 1842-47), which quite eclipsed the very ordinary works of Diogo Lemos (20 vols., 1786-1820), Sousa Monteiro (10 vols., 1838), and J. F. Pereira (3 vols., 1846-48), and the two chief English and French histories up to that date,—J. Dunham's (along with that of Spain) in Lardner's *Cabinet Cyclopædia* (1838-43), and Bouchot's, in Duruy's *Histoire Universelle* (1846). After the publication of Schaefer's *History*, and not uninfluenced by it, Alexandre Herculano commenced his great work, the *História de Portugal* (4 vols., 1848-53), in which he overthrew old legends and treated history scientifically. Owing, however, to the persecution and libellous pamphlets of such men as Francisco Recrio, J. D. Fonseca Pereira, and A. C. Pereira, he closed his work at the year 1279; but from 1854 to 1857 he published his *Da Origem e Estabelecimento da Inquisição em Portugal*, which also caused a great outcry. Nevertheless his example was followed, and a series of extremely good histories has been issued during the last twenty years, notably L. A. Rebello da Silva's *História de Portugal pendente XVI. e XVII. Séculos* (5 vols., 1860-71), which covers the failure of Dom Sebastian and the revolution of 1640; J. M. Latino Coelho's *História de Portugal desde os fins do XVIII. Século até 1814* (1874); J. F. Fonseca Benevides's *Las Rainhas de Portugal* (1878); and the extremely interesting and illustrated *História de Portugal* in 37 parts by Antonio Ennes, B. Ribeiro, Edouard Vidal, G. Lobato, L. Cordeiro, and Pinheiro Chagas (1877-88). The new historical school, headed by the viscount of Santarém, has also spent much time upon the conquests of the Portuguese in India, and Herculano edited the *Roteiro de Vasco de Gama*; nor must the admirable editions of the old Portuguese navigators and travellers published by the Hakluyt Society be omitted, or the well-known *Life of Prince Henry of Portugal*, by R. H. Major (London, 1868), which has been translated into Portuguese by J. A. Ferreira Brandão (1876). The new school has paid attention to the publication of the early chronicles of Portugal, and since 1856 several volumes of *Portugallia Monumenta Historica* have been issued by the Lisbon Academy of Sciences under the direction of Herculano; but this work was not neglected by their predecessors, as appears in the *Collecção dos Livros inéditos de História Portuguesa*, edited by J. F. Corrêa da Serra for the academy (11 vols., 1790-1804), and the *Collecção dos principais Auctores da História Portuguesa*, published in the same manner (1806). *Federa*, too, were not neglected during the present century; there exist two good collections: one, commenced by the viscount of Santarém as *Quadro elementar das Relações politicas e diplomaticas de Portugal*, and continued by Rebello da Silva for the academy as *Corpo diplomatico Portuguez*, extends from the early days of the monarchy till 1640 (36 vols., 1856-78); the other, which is practically a continuation of the first, is called a *Collecção dos Aatos publicos celebrados entre a Coroa de Portugal e as mais Potencias desde 1640 até ao Presente*, commenced by J. Ferreira-Borges de Castro, and continued by J. Judice Biker (8 vols., 1856-66). Two works on constitutional history here deserve mention, *Memorias para a História das Inquirições dos primeiros Reinados de Portugal*, published (1816) by the Lisbon College of Diplomats, and *Memorias para a História e Theoria das Côrtes*, by the viscount of Santarém (Lisbon, 1828). Before noticing books treating exclusively of the history of the present century, a few special works and articles ought to be enumerated, such as the chevalier de Jant's *Relations de la France avec le Portugal*

au temps de Mazarin, by Jules Tassin (Paris, 1877); Verri's *Evolution de Portugal* (Paris, 1878); Miguel d'Amica, *Les faits D. Sebastian* (Paris, 1886); R. Carré's *History of the Revolutions of Portugal from the Foundation of that Kingdom to the year 1877, with Letters of Sir R. Southwell during his Embassy there to the Duke of Ormond* (London, 1740), which are the best books on their respective subjects, and two articles in vol. II of the *Annuaire des Sciences Morales et Politiques*, "D. João II. e a Nobreza," by L. A. Rebelle de Silva, and "Apontamentos para a Historia da Conquista de Portugal por Philippe II.," by A. P. Lopes de Mendonça. The literature of the history of the last hundred years requires careful selection; the best work is, however, the *Historia da Guerra civil e do Estabelecimento do Governo parlamentar em Portugal*, by Simão José da Luz Soriano (8 vols., 1888-82); for the Peninsular War see, besides Napier's history, the *Historia geral da Invasão dos*

*Francos em Portugal*, by Accursio das Neves (Lisbon, 1810-11), and *Esboços históricos relativos a Guerra dos Trinta Anos da Península e as anteriores de 1801, de Rossellva e Cataluna*, by Claudio de Chaby (1853). The period of the war of Dom Miguel is best seen in the *Memorias para a Historia do tempo que durou a usurpação de D. Miguel*, by J. L. Freire de Carvalho (Lisbon, 1841-43); the *Historia da Liberdade em Portugal*, by J. G. Barros Cunha (Lisbon, 1889); *The Civil War in Portugal, and the Siege of Oporto by a British Officer of Honour* [Colonel Reddoch] (1835); and *The Wars of Succession of Spain and Portugal*, by William Bollaert (vol. I., 1870). For the ensuing period consult the *Despachos e Correspondência do Duque de Palmella* (3 vols., 1851-54); the *Correspondência oficial de D. João de Caminha com o Duque de Palmella* (1874); and the *Memoirs of the Duke of Saldanha*, by the count of Carnota (2 vols., 1880). (H. M. S.)

## PART III.—LITERATURE

Portugal has a distinct literature as well as a distinct history, and one which is intimately bound up with the growth of the nation. The biographies, histories, and travels of the 16th century are unrivalled of their age in brilliancy and vigour, while the poetry of a land where all men are singers is not only admirable in itself but illustrates a continuous and unaltered struggle between native and foreign schools. The period of the growth of national independence and of the victories over the Moors was that of the brilliant poetry of the Portuguese troubadours, which became at last truly characteristic; but the brilliancy speedily died away with peace and national unity, to be revived in the heroic period of Vasco da Gama and Albuquerque. For in the 16th century, after the classical school of Sá de Miranda had given a polish to the language, the national epics of Camões and his followers were produced, which might have yielded more lasting results had not the Spanish dominion paralysed all national life. In more modern times the reaction against mere imitations of foreign literature has resulted in the formation of a new native school by which much good work both in poetry and in historical research has already been accomplished.

**12th to 14th Century.**—The Portuguese, Gallegan, and Babil dialects, subdivisions of that form of the Lingua Romana Rustica spoken in Galicia and the western provinces of the Peninsula, will be more conveniently treated under SPAIN (LITERATURE). See also ROMANCE LANGUAGES. The remains of the early poets of Portugal are necessarily scanty, but they are sufficient to show that the courtly troubadours of the west were certainly not inferior to the more noted singers of Provence. In some respects they were even superior, since, not being tied to the forms of a merely literary language such as the Provençal, they were able to borrow both form and matter from a vigorous national poetry which can be traced through the different races which successively occupied Portugal. The "alalila," which afterwards developed into the "aravá," the earliest form of the epic, is probably a legacy from the original Turanian inhabitants; the "gracyolo," a short lyric with the refrain "ay" or "gal," was derived from their Celtic successors; the "cantos de ladino" are evidences of the Roman conquest, which in turn gave place to the "chacunas" or dance-songs of the Visigoths; while during the Arab dominion the seasons "serranilhas" and "cantos de amigo" found a place in the family "cancioneiros," which were then compiled in imitation of the divans or ritual songs of the ruling race. This national poetry, however, was for long affected in its literary form by foreign influences.

From the beginning of the reign of Afonso Henriques (1112) to the death of Dom Sancho II. (1248), the court was under direct Provençal influence; and it is not improbable that in 1143 the celebrated troubadour Marcabrun was himself attached to the suite of Donna Matilda on her marriage with Afonso Henriques, since he was certainly a visitor at the court in 1147. The poets Egas Moniz Coelho and Gonçalo Herminguez are commonly, though erroneously, referred to the time of Afonso Henriques, who was himself a poet; but the name (and poem) of only one undoubtedly Portuguese troubadour of this period has survived, João Soares de Panha (1145-1204). The history of Galician literature properly belongs to that of Spain, but it is important to remember that Portugal is perhaps even more than Castile the heir of its early efforts. Amongst the Galician poets who frequented the court of Sancho I. (1155-1211) and formed a strong opposition to the Italo-Provençal school were Afonso Gomez, Fernan Goncalves de Senabria, and João Soares de Pansa. The most famous of their Provençal rivals, who doubtless were the more readily welcomed owing to the king's marriage with a daughter of Raymond Berenger IV., count of Provence and king of Aragon, were Peire Vidal, Peire Valera, and Garandán o Velho, who in a "sirvente" written about 1210 incited the Christians to a crusade against the Moors. Afonso III. (1248-1279) returned from his residence at the court of St. Louis of France imbued with northern rather than with southern sentiments, and consequently during his reign French influences prevailed. The nobles who had accompanied him were "trouvères" rather than "troubadours"

and to one of them, Afonso Lopes de Baram, belongs the honour of writing the first Portuguese gesta, a *Gesta de Malizier*. Other celebrated poets of this Franco-Provençal school were the "privados," or court poets, João de Aboim, the author of several sirventes and romances, but, like De Baram, the writer also of cantos de amigo and cantos de ladino, Fernão Garcia Egazmanha, and João Garcia o Pinto, his brother. The privados were in their turn supplanted by Marim Moxa and Lorenzo and Diogo Pexelho, who belonged to the less privileged class of "segreiros," a term applied to those singers who wandered from court to court. The king's songs have been lost, or at least cannot be identified, but he is reputed to have been no mean poet and a sirvente against Alfonso X. of Castile, which appears from internal evidence to have been written by him, is still extant. To this period also belonged the privados Fernão Fernandes Cogominho, the writer of cantos de amigo and serranilhas, and Estevam Coelho, of whose works two lovely serranilhas remain of the purest Galician form and feeling. The works of these poets show that, notwithstanding foreign influence, the national forms had already obtained some degree of favour at court. Similarity in the literary language led to considerable intercourse between Portugal and Castile, and the Galician Pero da Ponte and Afonso Eanes de Coton were entertained by Afonso III., while the Portuguese poets Pero Gomes Barroso, Pero Gomes Charrinho, and Gonçalo Eanes do Vinhal enjoyed the patronage of Alfonso the Wise. On the accession of Diniz (1279-1325) the court literature showed the decided southern and Provençal tendencies of this king, who from the number, variety, and beauty of his songs was himself the greatest poet of his time. Educated by Aymeric d'Ebrard of Cahors, afterwards bishop of Coimbra, he at first affected the mannerisms of the decaying school of Provence. With the courts of Love which he introduced came the Limousin decasyllabic in place of the national octasyllabic metre, and the ancient forms were lost in the intricacies of the ritornelle. This king's songs are marked by an exaggerated subjectivism, but among them quaint and graceful "pastorelas" are found, full of poetic life and truth, which show that the king was not blind to the beauty of his people's lyrics. Admiration led to imitation, and the close of his reign is marked by a distinct literary revival of the national poetry, which at his hands received a polish it had somewhat lacked before. The effects of Diniz's influence pervade the whole of Portuguese poetry, for not only was he in his pastorelas the forerunner of the great pastoral school, but by sanctifying to literary use the national storehouse of song he perpetuated among his people, even to the present day, lyric forms of great beauty. Dom Diniz completely overshadows the poets who were his courtiers and contemporaries, but amongst them the most notable were Estevam de Guarda, Ayres Peres Veytron, Ray Goncalves, João Eanes, and João de Guilharda, though the last-named was rather a musician than a poet. Dom Afonso Sanchez, a natural son of Dom Diniz, wrote partly in the Limousin and partly in the Galician style, and another son, Dom Pedro, Conde de Barcellos, who compiled a "livro das cantigas" and a "nobiliario" or peerage, was the author of several poems, but in an affected strain, which marked the approaching decay of lyric poetry. With the reign of Afonso IV. (1325-1357) began the reaction of the Castilian language against the Portuguese, but the quarrels of Ferdinand (1367-1383) with Henry II. of Castile were the fortunate cause of the formation of a second national school. For amongst its founders were the Galician poets who took refuge at the court of Portugal, and who were followers of Maecias and Padron, including Vasco Pires de Camões, ancestor of the great Luis, while to this period must be properly assigned the poems of Egas Moniz Coelho and Gonçalo Herminguez.

Epic poetry was in Portugal as in Provence a later literary development than lyric. The popular *aravias* must have been poetry, numerous, to judge from the remains which are still found in the Azores and in the provinces of Beira and Algarves; and to the 13th century may be referred the *Lenda de Santa Iria* and the *Canta do Figueiral*. In its literary form the Breton "lai" was

known to Dom Pedro, brother of Afonso II. (1211-1223), and a few poems in this style with music attached were written by him. The *Roman de Brut* is also quoted by Diniz, but it was through the marriage of John I. with Philippa of Lancaster (1387) that a knowledge of the Arthurian cycle spread through the Peninsula and led to the popularity of the *Prophecies of Merlin* and kindred works down to the 16th century. The patriotic pride of the people, which had before found vent in the aravias or tales of contests with the Arabs, sought a new literary expression for the rising national greatness, and the parent of Camões's great epic is the poem in which Afonso Giraldes celebrates the victory won by the united armies of Portugal and Castile over the Moors at the battle of the Salado (1340). Only a small portion is extant, but it shows considerable vigour and foreshadows the development which national pride was afterwards to take in the *Lusiads*.

The revolt against the subjectivism of lyric poetry which appeared in the narrative spirit of the epic showed itself now in another form, and to Afonso IV. belongs the credit of fully appreciating the new tendencies. Acting under his instructions, Vasco de Lobeira (d. 1403) became the author of the first Portuguese novel by turning into prose the romance of *Amadis of Gaul*, which led the way for a host of imitations bearing a similar title. The historical records of this period are comprised chiefly in the *Chronica da Conquista do Algarve*, the *Livro velho das Linhagens*, and the *Nobiliário do Collegio dos Nobres*. The theological tendencies of the people are aptly illustrated by works which, although in Latin, deserve mention. They are the *Concordantia Morales* and *Interpretatio Mystica* by St Anthony of Lisbon (1195-1231), and the writings of Cardinal Alvares Paes (d. 1353). The most learned scholar, however, of this period was Pedro Hispano, who became Pope John XXI. (d. 1277), and whose universal learning recalled the days of the great schoolmen.

**15th Century.**—During this century lyric poetry was under the increasing influence of the Spanish school and of its leader Juan de Mena, whose praises were sung in some couplets by the infante Dom Pedro, son of John I. The chief imitators of this style were Luis de Azevedo, Ayres Telles (d. 1515), and Diogo Brandão (d. 1530). The Arthurian romances of *Dom Eurives* and *Brana-Flor* may be referred to this century; and the poems on the death of the infante Dom Pedro by Luis de Azevedo, and on the death of John II. by Diogo Brandão exhibit the literary form of the epic. The constable, son of Dom Pedro, felt the influence of the Italian Renaissance, and consequently became the founder of the Dantesque or allegorical school. His *Satira da felice e infelice Vida* is an allegorical piece of some merit, but a better specimen of this style is the *Visão* by Duarte de Brito, a compound of the *Roman de la Rose* and the *Divina Commedia*. The *Fingimento de Amore* by Fernão Brandão also possesses many beauties.

The principal prose works of the time are the *Book of the Chase* written for John I. (1383-1433), the vivid and interesting *Chronicles* of Fernão Lopes (1380-1459), the Froissart of Portugal, and the *Chronicles* of Gomes Eanes de Azurara (d. 1473), Ruy de Pina (1440-1520), and Duarte Galvão (1445-1517). King Edward himself (1433-1438) was the author of *The Faithful Counsellor* and *Instructions in Horsemanship*, while a *Treatise on Tactics* with several other works showed the powers of Afonso V. (1438-1481) as a general mathematician and natural philosopher, the cultivation of which may have been in part due to the lessons learned from the *Cyropædia* translated for him by Vasco de Lucena.

**16th and 17th Centuries.**—The golden age of Portuguese literature had now arrived, and to Bernardim Ribeiro (c. 1500) is due the honour of founding its characteristic school of romantic pastoral poetry. The rivers and mountains of his native land are the natural framework of a poet's fancy, and the revival of classical learning showed him in the *Eclogues* of Virgil a model which he was not slow to imitate. His *Eclogues*, written in "redondilhas" (octosyllabic nine or ten-lined stanzas), are accordingly the earliest in modern Europe, and, while replete with the charms and conceits of versification of the troubadours, show a truly poetic love of nature. He was also the writer of the first "sextinas" in redondilhas, and of many beautiful cantigas and elegies. To the same school, which was now the representative of all national feeling, belong Christovão Falcão, whose smaller poems are quite equal to those of Ribeiro, Garcia de Resende (1470-1554), compiler of the *Cancioneiro Geral*, a magnificent collection of poems by almost three hundred writers, beginning with Afonso Henriques, Gil Vicente (1470-1536), Jorge Ferreira de Vasconcellos (d. 1585), and Fernão Rodrigues Lobo Soropita (c. 1600). The last-named is chiefly known from three comic satires on the classical school and his *Introduction* to the poems of Camoens, which formed the basis of Faria e Sousa's *Commentary*. Except for the fact that a master-mind belongs to no school, Camoens himself might be claimed by these writers as a fellow-worker, for he was systematically either ignored or abused by the opposing school of classicists. His works are treated of at length elsewhere (see CAMOENS), but it is not out of place to remark here that his beauties are those of the national school and his defects the result of an imitation of the classicisms affected by his

opponents. These were the followers of the school founded by Francisco de Sá de Miranda (1495-1558) on his return from Italy, where he acquired a love not only for the Renaissance, whose influence had been already felt by Ribeiro, but for the forms in which the new culture found expression. Much praise is due to him for the polish he gave to his country's literature, but by his classical affectations and the favour he showed to the Spanish language, in which his best works were written, he sowed the seeds of that decay which afterwards overtook Portuguese poetry. The eclogues, epistles, odes, elegies, and sonnets of this school are often perfect in form and contain much real poetry, but the classicisms which at first are graceful in their novelty weary in the end by their unreality, and in the hands of inferior artists degenerate into mere stage properties, used to conceal the want of genius. The shepherds and shepherdesses are no longer the idealized peasants of the troubadours but courtiers in masquerade, and the sense of this lowering of the ideal is sufficient to destroy the pleasure which would otherwise be derived from the polished language and poetic imagination. The imitators of Miranda were very numerous; the chief among them were Antonio de Ferreira (1528-1569), who was Horatian rather than Virgilian in feeling, and consequently produced but inferior eclogues, while his didactic epistles were the earliest Portuguese examples of that style, Diogo Bernardes (d. 1599), whose sacred songs are particularly good, Pedro de Andrade de Caminha (d. 1589), Fernão Alvares do Oriente (b. 1540), Don Manuel de Portugal (d. 1606), and Estevão Rodrigues de Castro (1559-1637). Among the lyric poets of the 17th century the chief of those who by their satirical and comic verses showed an inclination to the national rather than the classical school were Thomas de Noronha (d. 1651) and Jacinto Freire de Andrade (1597-1657), author of the *Fabulas de Nereide* and of various songs and sonnets published in the *Fênix Renascida* (1716-1728). Antonio Barbosa Bacellar (1610-1663) was the first writer of "sandades," and was followed in the same style by Simão Torrezão Coelho (d. 1642). Sonnets were of course written by every man of culture, but they rarely rose above the standard of mediocrity. Those of Manuel de Faria e Sousa (1590-1649), Duarte Ribeiro de Macedo (1613-1680), and André Nunes da Silva (1630-1705) may, however, be reckoned among the best. The sacred poems of the last-named are also very good, but are surpassed by the *Jardim do Céu* by Eloi de Sá Sotomaior, and by the poems of Sister Violante do Céu (1601-1693). The didactic epistles of Antonio Alvares da Cunha (1626-1690) are fair specimens of this class of poem.

The truly heroic life of Portugal during this period naturally demanded to be sung in a fitting strain, and the 16th and 17th centuries were consequently the era of epic poems. The earliest of these was the *Creação do Homem* by André Falcão de Resende (d. 1598), which from its similarity in style has been often attributed to Camoens (1524-1579), whose *Lusiads* appeared in 1572. Though the sole masterpiece of the country and the age, this last not unworthily eclipses other epics in which the brilliant passages are more or less numerous. Such are the *Primeiro Cerco de Diu* by Francisco de Andrade (1540-1614), the *Naufragio de Sepulveda* and the *Segundo Cerco de Diu* by Jeronymo Corte-Real (1540-1593), both rather above the average, the *Elegiada* (1588) by Luis Pereira Brandão, the *Afonso Africano* (1611) by Vasco Monsinho de Quebedo, who shares with Corte-Real the honour of ranking next after Camoens, the *Ulysséa* by Gabriel Pereira de Castro (1571-1632), the *Viriato Tragico* by Braz Garcia Mascarenhas (1596-1656), the *Malaca Conquistada* by Francisco de Sá de Menezes (d. 1664), the *Ulyssipo* by Antonio de Souza de Macedo (1606-1682), and the *Destruição de Hespanha* (1671) by André da Silva Mascarenhas.

The drama in Portugal was stifled in its birth. The miracle-drama, plays of the people attained a high degree of excellence in the "autos" or sacred Christmas plays of Gil Vicente (1470-1536), but this writer was born half a century too soon for his work. His comedies, of which the best is *Inez Pereira*, are full of the rough wit which is found in the early Latin writers, but show a want of polish and dramatic conception which is fatal to their claims to high rank as works of art. The comedies of his contemporaries, Antonio Prestes, Jorge Pinto, and Jeronymo Ribeiro Soares, all show considerable talent, and the *Eufrosina* of Jorge Ferreira de Vasconcellos (d. 1585) most nearly approaches to a modern standard of excellence. Francisco Manuel de Mello (1611-1666) was the author in Portuguese of the *Auto do Fidalgo Aprendiz* as well as of several poems, but most of his works are in the Spanish language. Among the classicists Miranda was the author of the comedies *Os Estrangeiros* and *Os Vilhalpandos*, but his plays are inferior to those of Ferreira, whose dramatic works are in some respects superior to his poems. The chief of them, which was produced only a few years later than the *Sophonisba* of Trissino, is the tragedy *Incê de Castro*, but, though his subject was so fine, his treatment of it was not altogether satisfactory. There are also several plays by Camoens; but the influence of the Spanish language was by this time irresistible, and the result was that all serious dramas were written in Castilian, while Portuguese was reserved only for the lighter and more popular pieces, the best of which were collected

known to Dom Pedro, brother of Afonso II. (1211-1223), and a few poems in this style with music attached were written by him. The *Roman de Brut* is also quoted by Diniz, but it was through the marriage of John I. with Philippa of Lancaster (1337) that a knowledge of the Arthurian cycle spread through the Peninsula and led to the popularity of the *Prophecies of Merlin* and kindred works down to the 16th century. The patriotic pride of the people, which had before found vent in the aravias or tales of contests with the Arabs, sought a new literary expression for the rising national greatness, and the paragon of Camões's great epic is the poem in which Alfonso Giraldez celebrates the victory won by the united armies of Portugal and Castile over the Moors at the battle of the Salado (1340). Only a small portion is extant, but it shows considerable vigour and foreshadows the development which national pride was afterwards to take in the *Lusiads*.

The revolt against the subjectivism of lyric poetry which appeared in the narrative spirit of the epic showed itself now in another form, and to Afonso IV. belongs the credit of fully appreciating the new tendencies. Acting under his instructions, Vasco de Lobeira (d. 1403) became the author of the first Portuguese novel by turning into prose the romance of *Amadis of Gaul*, which led the way for a host of imitations bearing a similar title. The historical records of this period are comprised chiefly in the *Chronica da Conquista do Algarve*, the *Livro velho das Linhagens*, and the *Nobiliário do Collegio dos Nobres*. The theological tendencies of the people are aptly illustrated by works which, although in Latin, deserve mention. They are the *Concordantia Morales* and *Interpretatio Mystica* by St Anthony of Lisbon (1195-1231), and the writings of Cardinal Alvaro Paes (d. 1353). The most learned scholar, however, of this period was Pedro Hispano, who became Pope John XXI. (d. 1277), and whose universal learning recalled the days of the great schoolmen.

**15th Century.**—During this century lyric poetry was under the increasing influence of the Spanish school and of its leader Juan de Mena, whose praises were sung in some couplets by the infante Dom Pedro, son of John I. The chief imitators of this style were Luis de Azevedo, Ayres Telles (d. 1515), and Diogo Brandão (d. 1530). The Arthurian romances of *Dom Eurites* and *Branca-Flor* may be referred to this century; and the poems on the death of the infante Dom Pedro by Luis de Azevedo, and on the death of John II. by Diogo Brandão exhibit the literary form of the epic. The constable, son of Dom Pedro, felt the influence of the Italian Renaissance, and consequently became the founder of the Dantesque or allegorical school. His *Satira da felice e infelice Vida* is an allegorical piece of some merit, but a better specimen of this style is the *Visão* by Duarte do Brito, a compound of the *Roman de la Rose* and the *Divina Commedia*. The *Fingimento de Amore* by Fernão Brandão also possesses many beauties.

The principal prose works of the time are the *Book of the Chase* written for John I. (1383-1433), the vivid and interesting *Chronicles* of Fernão Lopes (1380-1459), the Froissart of Portugal, and the *Chronicles* of Gomes Eanes do Azurara (d. 1473), Ruy de Pina (1440-1520), and Duarte Galvão (1445-1517). King Edward himself (1433-1438) was the author of *The Faithful Counsellor* and *Instructions in Horsemanship*, while a *Treatise on Tactics* with several other works showed the powers of Afonso V. (1438-1481) as a general mathematician and natural philosopher, the cultivation of which may have been in part due to the lessons learned from the *Cyropædia* translated for him by Vasco de Lucena.

**16th and 17th Centuries.**—The golden age of Portuguese literature had now arrived, and to Bernardim Ribeiro (c. 1500) is due the honour of founding its characteristic school of romantic pastoral poetry. The rivers and mountains of his native land are the natural framework of a poet's fancy, and the revival of classical learning showed him in the *Eclogues* of Virgil a model which he was not slow to imitate. His *Eclogues*, written in "redondilhas" (octosyllabic nine or ten-lined stanzas), are accordingly the earliest in modern Europe, and, while replete with the charms and conceits of versification of the troubadours, show a truly poetic love of nature. He was also the writer of the first "sextinas" in redondilhas, and of many beautiful cantigas and elegies. To the same school, which was now the representative of all national feeling, belong Christovão Falcão, whose smaller poems are quite equal to those of Ribeiro, Garcia de Resende (1470-1554), compiler of the *Cancioneiro Geral*, a magnificent collection of poems by almost three hundred writers, beginning with Afonso Henriques, Gil Vicente (1470-1536), Jorge Ferreira de Vasconcellos (d. 1585), and Fernão Rodrigues Lobo Soropita (c. 1600). The last-named is chiefly known from three comic satires on the classical school and his *Introduction* to the poems of Camões, which formed the basis of Faria e Sousa's *Commentary*. Except for the fact that a master-mind belongs to no school, Camões himself might be claimed by these writers as a fellow-worker, for he was systematically either ignored or abused by the opposing school of classicists. His works are treated of at length elsewhere (see CAMOENS), but it is not out of place to remark here that his beauties are those of the national school and his defects the result of an imitation of the classicisms affected by his

opponents. These were the followers of the school founded by Francisco de Sá de Miranda (1495-1558) on his return from Italy, where he acquired a love not only for the Renaissance, whose influence had been already felt by Ribeiro, but for the forms in which the new culture found expression. Much praise is due to him for the polish he gave to his country's literature, but by his classical affectations and the favour he showed to the Spanish language, in which his best works were written, he sowed the seeds of that decay which afterwards overtook Portuguese poetry. The eclogues, epistles, odes, elegies, and sonnets of this school are often perfect in form and contain much real poetry, but the classicisms which at first are graceful in their novelty weary in the end by their unreality, and in the hands of inferior artists degenerate into mere stage properties, used to conceal the want of genius. The shepherds and shepherdesses are no longer the idealized peasants of the troubadours but courtiers in masquerade, and the sense of this lowering of the ideal is sufficient to destroy the pleasure which would otherwise be derived from the polished language and poetic imagination. The imitators of Miranda were very numerous; the chief among them were Antonio de Ferreira (1528-1569), who was Horatian rather than Virgilian in feeling, and consequently produced but inferior eclogues, while his didactic epistles were the earliest Portuguese examples of that style, Diogo Bernardes (d. 1599), whose sacred songs are particularly good, Pedro de Andrade de Caminha (d. 1539), Fernão Alvares do Oriente (b. 1540), Don Manuel de Portugal (d. 1606), and Estevão Rodrigues de Castro (1559-1637). Among the lyric poets of the 17th century the chief of those who by their satirical and comic verses showed an inclination to the national rather than the classical school were Thomas do Noronha (d. 1651) and Jacinto Freire de Andrade (1597-1657), author of the *Fabulas de Narciso* and of various songs and sonnets published in the *Fénix Renascida* (1716-1728). Antonio Barbosa Bacellar (1610-1663) was the first writer of "saudades," and was followed in the same style by Simão Torreão Coelho (d. 1642). Sonnets were of course written by every man of culture, but they rarely rose above the standard of mediocrity. Those of Manuel de Faria e Sousa (1590-1649), Duarte Ribeiro de Macedo (1618-1680), and André Nunes da Silva (1630-1705) may, however, be reckoned among the best. The sacred poems of the last-named are also very good, but are surpassed by the *Jardim do Céu* by Eloi da Sá Sotomaior, and by the poems of Sister Violante do Céu (1601-1693). The didactic epistles of Antonio Alvares da Cunha (1626-1690) are fair specimens of this class of poem.

The truly heroic life of Portugal during this period naturally demanded to be sung in a fitting strain, and the 16th and 17th centuries were consequently the era of epic poems. The earliest of these was the *Creação do Homem* by André Falcão do Resende (d. 1693), which from its similarity in style has been often attributed to Camões (1524-1579), whose *Lusiads* appeared in 1572. Though the sole masterpiece of the country and the age, this last not unworthily eclipses other epics in which the brilliant passages are more or less numerous. Such are the *Primeiro Cerco de Diu* by Francisco de Andrade (1540-1614), the *Naufragio de Sepulveda* and the *Segundo Cerco de Diu* by Jeronymo Corte-Real (1540-1593), both rather above the average, the *Elegia da* (1588) by Luis Pereira Brandão, the *Afonso Africano* (1611) by Vasco Mousinho do Quebedo, who shares with Corte-Real the honour of ranking next after Camões, the *Ulysséa* by Gabriel Pereira de Castro (1571-1632), the *Viriato Tragico* by Braz Garcia Mascarenhas (1596-1656), the *Malaca Conquistada* by Francisco do Sá de Menezes (d. 1664), the *Ulyssip* by Antonio do Souza do Macedo (1606-1682), and the *Destruição de Hespanha* (1671) by André da Silva Mascarenhas.

The drama in Portugal was stilled in its birth. The miracle-Drama plays of the people attained a high degree of excellence in the "autos" or sacred Christmas plays of Gil Vicente (1470-1536), but this writer was born half a century too soon for his work. His comedies, of which the best is *Inez Pereira*, are full of the rough wit which is found in the early Latin writers, but show a want of polish and dramatic conception which is fatal to their claims to high rank as works of art. The comedies of his contemporaries, Antonio Prestes, Jorge Pinto, and Jeronymo Ribeiro Soares, all show considerable talent, and the *Eufrosina* of Jorge Ferreira de Vasconcellos (d. 1586) most nearly approaches to a modern standard of excellence. Francisco Manuel do Mello (1611-1666) was the author in Portuguese of the *Auto do Fidalgo Aprendiz* as well as of several poems, but most of his works are in the Spanish language. Among the classicists Miranda was the author of the comedies *Os Estrangeiros* and *Os Vilhalpandos*, but his plays are inferior to those of Ferreira, whose dramatic works are in some respects superior to his poems. The chief of them, which was produced only a few years later than the *Sophonisba* of Trissino, is the tragedy *Inez de Castro*, but, though his subject was so fine, his treatment of it was not altogether satisfactory. There are also several plays by Camões; but the influence of the Spanish language was by this time irresistible, and the result was that all serious dramas were written in Castilian, while Portuguese was reserved only for the lighter and more popular pieces, the best of which were collected

those of Garrett, who is also the author of both the earliest and the best examples of the modern Portuguese drama, *Gil Vicente*, *Alfageme*, and *Luis de Sousa*. The principal works of Castilho are *A Primavera*, *Amor e Melancolia*, and *Exercícios Poéticos*; and the writers who may chiefly be claimed as his followers are Sarmiento, J. M. de Costa e Silva the dramatist, Cabral de Mello, and Fernandes Leitão. The publication in 1848 of *O Trovador*, a collection of modern lyrics, marks the foundation of the school of Coimbra. Its leader, João de Lemos, the lyric poet, found fellow-workers in José Freire de Serpa, the impressionable author of *Solões*, and José da Silva Mendes Leal, author of the dramas *A Alva Estrela*, *A Mãe de Silva*, and *Os Homens de Marmore*, and various lyric poems. The most popular modern poet Luis Augusto Palmeirim, the dramatist A. Pereira da Cunha, Antonio de Serpa, and João de Andrade Corvo, author of the novel *Um Anno da Corte*, all belong to this school, the prevailing characteristic of which at its foundation was a profound admiration for Chateaubriand and his royalist and religious opinions. The second phase of this school dates from the *Novo Trovador*, in which the influence of Aimé Martin and Krause on its originator Soares de Passos is plainly visible. The poems of Passos are tinged with a melancholy which presaged his early death, and he philosophizes in the *Firmamento*, the *Escravo*, and the *Morte de Socrates* somewhat in the same strain as the English Lake poets. The third phase of the school of Coimbra is represented by the *Flores do Campo* and *Folhas Soltas* of João de Deus, the poet of love and revolution. Of the same school the *Visão dos Tempos* by Theophilo Braga is an attempt at a new revelation, and the *Odes Modernas* by Anthero do Quental are socialistic, but both writers show more than ordinary power. Other modern poets are Alberto Telles, Sousa Viterbo, Candido de Figueiredo, Gomes Leal, Thomas Ribeiro, A. J. Viale, and Guilherme de Azevedo. The plays of C. C. Branco and Ernesto Biester are above the average, and King Luis has worthily followed the traditions of his race in his translations of the plays of Shakespeare. The historical novels of Herculano are much admired by his countrymen, as well as those of L. A. Rebello da Silva; and the works of J. G. Gomes Coelho (Julio Diniz), A. de Oliveira Marreca, Mendes Leal, Bernardim Ribeiro, Arnal do Gama, Teixeira de Vasconcellos, and Camillo Castello Branco, with his accuracy of description, have some reputation; but the best modern novel, judged by an English standard, is *O Crime do Padre Amaro* by Eça de Queiroz. As the growth of Portuguese independence was coeval with the work of the troubadours, and the discoveries and conquests of the heroic age gave birth to the epic of Camocns, so, in like manner, the political revival of the 19th century has given rise to a school of great historians, the chief of whom was Alexandre Herculano. The exile of Herculano had brought him into contact with both English and French romanticism, as appears in his early poems and his historical novels, in which the influence of Lamartine and Scott is plainly visible, but in later life he was attracted to the new German school of historians founded by Ranke, and perceived that his true vocation was scientific history. His chief work has been the disentangle-

Modern  
v. 352.

ment of the early history of Portugal from the mass of legends which had clustered round it, and his *History of Portugal* and *The Origin of the Inquisition in Portugal* are lasting monuments of industry and criticism. But Herculano perceived that, before a true knowledge could be gained of Portuguese history, a critical study must be made of early documents, so, using his official position, he commenced the publication for the academy of a magnificent edition of the *Origines* of Portuguese history. The viscount of Santarem began a similar work in his collections of *Federa*, though his fame will rest rather on his researches into the history of the great maritime discoveries of the 15th and 16th centuries. L. A. Rebello da Silva continued the work of Santarem in the publication of the *Corpo Diplomatico*, and his *History of Portugal in the 17th and 18th Centuries* is only inferior to the great work of Herculano. These historians inspired many others, among whom may be mentioned Fonseca Benevides, F. F. de la Figanerie, Claudio de Chaby, and Simão José da Luz Soriano. The strength of this school is no doubt partly due to the extreme vigour of the reactionaries who were first called into existence by Herculano's attacks on superstitious legends. Their work is brilliant if not convincing, and it would not therefore be right to pass over without mention such names as F. Recreio, Pinheiro Chagas, and Affonso Ennes. In general literature the name of Francisco Alexandre Lobo (1763-1844) stands out prominently as the foremost man of the century, and the Portuguese equal of De Maistre, whilst Thomas de Carvalho, Rodrigo da Fonseca, Cesar Machado, Lopes de Mendonça, F. Adolpho Coelho, Theophilo Braga, Innocencio Francisco da Silva, and F. D. Vieira have all won a position as critics and essayists. Political liberty has gone hand in hand with the freedom of the press, and here again Herculano appears as the founder of the *Panorama*, in which he had the assistance of most of the writers above-mentioned. Besides these the most influential journalists are Teixeira de Vasconcellos, Rodrigues de Sampaio, and J. M. Latino Coelho. While the press remains free and can boast of such writers Portuguese literature will certainly increase in strength and vigour, and maintain the feeling of national pride and independence which appears so strongly in the works of Garrett and Herculano, and will always prevent a union with Spain.

**Bibliography.**—For the general history of Portuguese literature, Bouterwek, *Hist. of Span. and Port. Literature* (London, 1823); Sismondi, *Hist. of the Literature of the South of Europe* (London, 1823); and J. F. Denis, *Résumé de l'Hist. litt. de Portugal* (Paris, 1826) may be consulted; also the "Notice on Literature" by Theo. Braga, in vol. I. of Vieira's *Grande Dicionário* (Oporto, 1871), and the same writer's *Introductions to the Antologia Portuguesa* (Oporto, 1876) and the *Parnaso Portuguez Moderno* (Lisbon, 1877). For the troubadour period, see the *Introductions to Tróvas e Cantares*, ed. Varnhagen (Madrid, 1849), and the *Cancioneiro Portuguez*, ed. Braga (Lisbon, 1876). The *Memorias* of the academy and the *Introduction to the Parnaso Lusitano* (Paris, 1826) may be consulted for the classical period; and the *Memorias de Litt. contemporânea* by A. P. Lopes de Mendonça (Lisbon, 1855) and *La Littérature Portugaise* by J. M. Pereira da Silva (Rio, 1866) give a fair account of contemporaneous literature. The best biographical dictionaries are the *Bibliotheca Lusitana* by Machado (Lisbon, 1741) and the *Dicionário Bibliographico Portuguez* by Innocencio F. da Silva (Lisbon, 1858). (H. B. B.)

**PORUS**, the name of the Indian king who withstood Alexander the Great on the banks of the Hydaspes (Jhelum). He was afterwards confirmed in his kingdom by the conqueror, and still held the position of a Macedonian satrap when assassinated some time between 321 and 315 B.C. See *INDIA*, vol. xii. pp. 786, 787, and *PERSIA*, vol. xviii. p. 536. His cousin, also named Porus, with whom he was on bad terms, ruled over Gandaris beyond the Hydraotes (Ravi), and was subdued by Hephæstion.

**POSEIDON**, the ancient Greek god of the sea and of water generally, was fabled to be the son of Cronus and Rhea, and brother of Zeus and Pluto. When the three brothers deposed their father Cronus the kingdom of the sea fell by lot to Poseidon. With his wife, Amphitrite, he dwelt in the depths of the sea; at Ægæ he had a golden house beneath the waves. In his hand he bore a trident (a three-pronged fish-spear), wherewith he lashed the sea into fury. But, while he caused storms and shipwrecks, he could also send favouring winds. He was the god of navigation, adored by all who sailed the sea. His temples stood especially on headlands and isthmuses. As god of the sea he disputed with other deities for the possession of the land—with Athene for Athens and Træzen, with Helios for Corinth, with Hera for Argos, with Zeus for Ægina, &c. Earthquakes were thought to be produced by Poseidon shaking the earth,—hence his epithet of

"Earth-shaker," and hence he was worshipped even in inland places, like Apamea in Phrygia, which had suffered from earthquakes. Hence also may have arisen the custom in some places of sacrificing moles to him. The great sea-wave which often accompanies an earthquake was also his work; the destruction of Helice in Achaia by such a wave (373 B.C.) was attributed to his wrath. Once when an earthquake shook the ground where a Spartan army was encamped, the whole army sang a hymn to Poseidon. The island of Delos was thought to have been raised by him from the bottom of the sea, and in 237 B.C., when a new island appeared between Thera and Therasia, the Rhodians founded a temple of Poseidon on it. Thessaly was said to have been a lake until this god opened a way for the waters through the Vale of Tempe. Poseidon was also the god of springs, which he produced by striking the rock with his trident, as he did on the acropolis of Athens when he was disputing with Athene for the sovereignty of Athens. This dispute was represented on the western pediment of the Parthenon. As he gave, so he could withhold springs of water; thus the waterless neighbourhood of Argos was supposed to suffer from his anger. Black bulls were sacrificed to him; in Ionia and Thessaly bull-fights took place in his honour; at a festival of his at Ephesus the cupbearers were called "bulls," and the god himself was surnamed "Bull Poseidon." The horse was

especially associated with his worship; he was said to have produced the first horse by striking the ground in Thessaly with his trident. At a fountain in Argolis horses bitted and bridled were sacrificed to him by being drowned in the water, and similarly Sextus Pompeius sought to propitiate him by throwing horses into the sea. He bore the surname of "Horse Neptune," and was regarded as the tamer as well as the creator of the steed. His worship was thought by Herodotus to have been derived from the Libyans. It had special seats in Thessaly, Boeotia, and the Peloponnesus. He had a famous cave-like temple at Tanarum in Laconia. On the island of Tenos he was worshipped as the physician, and crowds gathered from the neighbouring islands to offer sacrifice. At Mycale in Asia Minor the Panionium, or place of general assembly of the Ionian Greeks, was sacred to him. In the Trojan War Poseidon sided with the Greeks because he had been cheated of his reward by Laomedon, the former king of Troy, for whom he had built the city walls. The offspring of his numerous amours were mostly wild and cruel like the sea; such were the Læstrygones, Polyphemus, Cycnus, Antæus, Busiris, Procrustes, Sciron, and Orion. Alcinous, king of the sea-faring Phæacians in the *Odyssey*, traced his lineage to Poseidon. By far the most famous of the festivals of Poseidon was that celebrated every second year on the Isthmus of Corinth and hence called the "Isthmian festival" (see vol. x. p. 65). Pine trees were sacred to Poseidon; a row of them stood close to his temple on the isthmus. Amongst the Ionians the stormy month which precedes the winter solstice was called by the name of Poseidon. He was described as dark-haired, broad-breasted, and blue-eyed. In works of art he appeared holding a trident and with a dolphin on his hand or under his feet; sometimes he was represented riding a bull, a horse, or a sea-horse, or in a chariot, often surrounded by the Tritons, Nereids, and other fabulous creatures of the sea. There were colossal statues of him at Helice in Achaia, on the Isthmus of Corinth (set up by the Greeks after the Persian wars), and at Tenos. The derivation of his name is uncertain; some refer it to the same root as πόρος, ποταμός, &c.; others compare πόρνια. In modern Greece St Nicholas has taken the place of Poseidon as patron of sailors. But the Zacynthians have a special sea-god, half man, half fish, who dwells under the sea, rides on dolphins or in a car drawn by dolphins, and wields a trident. He seems to combine the attributes of Poseidon and Nereus. For the Roman sea-god, see NEPTUNE.

POSEN, a province in the east of Prussia, with an area (11,180 square miles) nearly equal to that of Belgium, is bounded on the N. by the province of Prussia, on the E. by Russian Poland, on the S. by Silesia, and on the W. by Brandenburg. It belongs physically to the great north German plain, and consists of a low plateau intersected by the beds of the Netze, the Warthe, and the Obra. The three rivers just named drain into the Oder, but part of the province falls within the basin of the Vistula, which forms the frontier for a short distance on the north-east. The surface of the whole district is dotted with small lakes and ponds, and there are many broad fens and marshes. The soil on the whole is light and sandy, but much of the land reclaimed in the boggy districts is very fertile. Upwards of 61 per cent. of the area is under cultivation, while 13 per cent. is occupied by pasture and meadows and 20 per cent. by forests. The principal crops are wheat, rye, oats, barley, potatoes, and hops (compare PRUSSIA); the vine is cultivated to some extent in the south-west corner, and tobacco is also grown. The marshy tracts often afford excellent pasture and support large numbers of cattle, sheep, and goats. The mineral resources of the province are practically restricted to brown coal and salt,

about 26,000 tons of the former and 75,000 tons of the latter being raised in 1882. The industry is confined to a few points, and is of comparatively little importance. Besides beer and brandy, the chief products are machinery, cloth, tobacco, and bricks. Trade, carried on briskly in timber and agricultural produce, is facilitated by the network of navigable rivers and canals. Both industry and trade are somewhat cramped by the duties imposed at the Russian frontier. The population of the province in 1880 was 1,703,397, including 1,112,962 Roman Catholics, 532,498 Protestants, and 56,609 Jews. The Roman Catholics are mainly Poles, of whom there are about 950,000 in Posen, while the great bulk of the 750,000 Germans are Protestants. About 65 per cent. of the population is returned as "rural" in spite of the large number of so-called "towns," only seven of which, however, have more than 10,000 inhabitants. The largest are Posen and Bromberg. The province of Posen enjoys the unenviable distinction of being the worst educated corner of the German dominions, a fact illustrated by the high ratio of illiterate recruits (9.75 per cent. in 1882-83). It is represented in the German reichstag by fifteen and in the Prussian parliament by twenty-nine deputies.

*History.*—The history of the district of Posen, comprehending great part of the cradle of the old kingdom of Poland, including its most ancient capital (Gnesen), falls properly within the scope of the article POLAND (q.v.). Its political connexion with Prussia began in 1772, when the districts to the north of the Netze fell to the share of that power in the first partition of Poland. The rest followed in 1793, and was united with the Netze district to form the province of South Prussia. After the peace of Tilsit Posen was incorporated with the grand-duchy of Warsaw, but in 1815 it reverted to Prussia under the style of the "grand-duchy of Posen." In 1843 the Polish inhabitants of the province revolted and had to be put down by force; and a thoroughly harmonious union of the two elements of the population is still unattained.

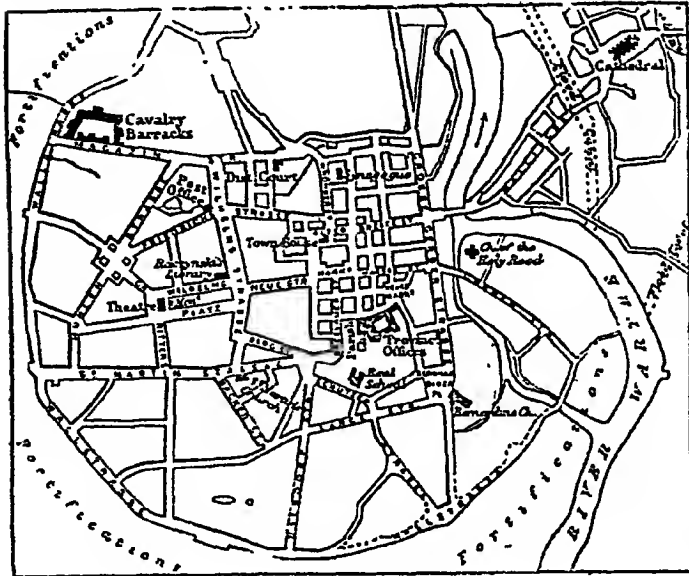

The tide of German immigration into Posen began at an early period and flowed very strongly in the 13th and following centuries. The industrious German settlers were heartily welcomed by the Polish nobles and were the founders of most of the towns, in which they lived after their own customs and were governed by their own laws. They established the few manufactures of which the district can boast, introduced the cultivation of hops, reclaimed the waste soil, and did much to improve agriculture generally. In the 16th century Protestantism was widely diffused by their means. A strong reaction, however, set in in the following century, and persecution of the Protestants went hand in hand with the ravages of war in hastening the political, intellectual, and agricultural decline of the territory. By the 18th century the burghers had sunk to the level of "städtische Bauern," or peasants with municipal privileges, and poverty and misery were widely spread. The Prussian rule, in spite of many defects, proved so beneficial that even Napoleon was compelled to praise it.

Posen contains a numerous Polish noblesse, many of the members of which are very poor. A double transformation is going on in the ownership of the ground, the large estates passing into the hands of the peasants and Polish proprietors giving place to German. A few years ago between 60 and 70 per cent. of the soil was occupied by "latifundia," while at present it is pretty equally divided between those and peasant holdings. In the four years 1873-81, inclusive, the land in the possession of Germans increased at the expense of Polish landowners by upwards of 160,000 acres. The peasant-farmers are generally deeply in debt, partly owing to the educational and communal burdens, but mainly owing to the pernicious custom of "Leibgedinge," according to which an able-bodied man in the prime of life will give up his holding in return for an annuity from his successor. In some instances two annuitants of this kind are found living on the same small patch of ground in addition to the actual cultivator.

POSEN (Polish, *Poznań*), capital of the above province, the seat of a Roman Catholic archbishop, and the headquarters of a corps of the German army, is situated at the confluence of the Cybina and Warthe, 150 miles to the east of Berlin and 90 miles to the north of Breslau. It is a fortress of the first rank and of great strategic importance; the works consist of a citadel and inner line of bastions, and an outer circle of twelve detached forts. The principal part of the town lies on the west bank of the Warthe, and comprises the so-called Altstadt and the

well-built modern quarter that has sprung up under the Prussian régime. On the other bank is the Wallischei, a poor district inhabited by Poles. Among the older buildings none calls for remark except the town-house, a quaint specimen of the Slavonic adaptation of Romanesque forms. The chief modern buildings are the various military and public offices, the law courts, the theatre, the real school, and the Raczynski library. The churches are devoid of architectural interest, but the cathedral contains numerous interesting objects of art, including two bronze-gilt statues

Plan of Posen.

of the first Christian kings of Poland, by Rauch. The manufactures of Posen are multifarious enough, including machinery, carriages, tobacco, copper boilers and vats, military requisites, chemicals, &c.; but there is nothing that can be called a staple industry. A lively trade is carried on in the agricultural products of Russia and Poland, and several well-attended fairs and markets are held. In 1880 Posen contained 65,713 inhabitants, including 35,725 Roman Catholics, 22,869 Protestants, and 7063 Jews. The German inhabitants are at present considerably more numerous than the Poles, though it would seem that the latter have increased in a greater ratio since 1875. The Jewish element is stronger here (10·7 per cent.) than in any other town in Germany. The garrison consists of 7000 men.

Posen, one of the oldest towns in Poland and the residence of some of the early Polish princes, became the seat of a Christian bishop towards the end of the 10th century. The original settlement was on the east bank of the Warthe, but the new or German town, established on the west bank about the year 1250, soon became the more important half of the double city. Posen was a royal free town, and was directly represented in the Polish diet down to 1733. In the Middle Ages it became a great depôt of the trade between Germany and the west of Europe on the one hand and Poland and Russia on the other. Numerous foreign merchants took up their abode here, including a strong colony of Scotsmen, who exported raw produce to Edinburgh. The town attained the climax of its prosperity in the 16th century, when its population is variously estimated at from 30,000 to 30,000. The intolerance shown to the Protestants, the troubles of the Thirty Years' War, the visitation of the plague, and other causes, however, soon conspired to change the state of affairs, and in the 18th century the town had only 5000 inhabitants. New life was infused into it on its annexation by Prussia at the second partition of Poland, and since then its progress has been limited only by its position as a fortress. The relations of the German and Polish elements of the population continue to be somewhat strained.

POSIDONIUS, a distinguished Stoic philosopher, the most learned man of his time (c. 130-50 B.C.) and perhaps of all the school; by birth a Syrian from Apamea, a pupil of Panætius, he spent after his teacher's death many years in travel and scientific researches in Spain (particularly at Gades), Africa, Italy, Gaul, Liguria, Sicily, and

on the eastern shores of the Adriatic. When he settled as a teacher at Rhodes his fame attracted numerous scholars; next to Panætius he did most, by writings and personal intercourse, to spread Stoicism in the Roman world; he became well known to many of the leading men, as Marius, Rutilius Rufus, Pompey, and Cicero. The last-named studied under him (78-77 B.C.), and speaks as his warm admirer and personal friend.

Strabo mentions him as a contemporary. The date of his birth has not been fixed; it may have been 135, 130, or 125 B.C.; according to Lucian, he lived to be eighty-four. He visited Rome—e.g., in 86 B.C. on an embassy; but it is doubtful if he ever resided there as a teacher. His works, now lost, were written in an attractive style and proved a mine of information to later writers. The titles and subjects of more than twenty of them are known. In common with other Stoics of the middle period, he displays eclectic tendencies. His admiration for Plato led him to write a commentary on the *Timæus*; in another way it is shown by important modifications which he made in psychological doctrine. Unquestionably more of a polymath than a philosopher, he appears to us unceritcal, or credulous even, and superficial. But at the time his spirit of inquiry provoked Strabo's criticism as something alien to the school (*τὸ ἀντιλογικὸν καὶ τὸ ἀπιστορικόν, ὅπερ ἐκκλινόντων οἱ ἡμέτεροι*). In natural science he took a genuine interest, as his contributions to geography, natural history, mathematics, and astronomy sufficiently attest. He sought to determine the distance and magnitude of the sun, to calculate the diameter of the earth and the influence of the moon on the tides. His history of the period from 146 to 88 B.C., in fifty-two books, must have been a valuable storehouse of facts. Cicero, who submitted to his criticism the memoirs which he had written in Greek of his consulship, made use of writings of Posidonius in *De Natura Deorum*, b. ii., and *De Divinatione*, b. i., and the author of the pseudo-Aristotelian treatise *De Mundo* also borrowed from him.

Zeller, *Philosophie der Griechen*, iii. 1, 570-584 (in Eng. trans., *Eclecticism*, 56-70); C. Müller, *Fragmenta Historicorum Græcorum*, iii. 243-256; J. Bake, *Posidonii Rhodii Reliquiæ*, Leyden, 1810 (a valuable monograph); R. Schæppig, *De Posidonio rerum gentium terrarum scriptore*, Berlin, 1869; R. Hirzel, *Untersuchungen zu Ciceros philosophischen Schriften*, i. 191 sq.; ii. 257 sq., 325 sq., 477-535, 750-759; iii. 342-373 (Leipzig, 1877). See STOICISM.

POSITIVISM, or POSITIVE PHILOSOPHY. See COMTE.

POSSESSION is a legal term derived from Roman law. The Roman conception of possession has been generally adopted, but the Roman deductions from the conception have not been universally followed. The subject of possession, in itself a difficult one, has become more difficult owing to the various senses in which the term has been interpreted. Thus it has been said to be either a right or a fact conferring a right, or both together. The latter is the view of Savigny, the leading authority upon the subject (*Recht des Besitzes*, translated by Sir Erskine Perry, 1848). Further, there is a want of agreement among legal writers as to the amount of right or rights that it confers. All that can be said with safety is that possession stands in a position intermediate between simple detention and absolute ownership, and that it implies two elements, a physical and a mental one,—physical detention and mental intention to hold the thing possessed as one's own. In the words of the *Digest*, "Apiscimur possessionem corpore et animo, neque per se animo aut per se corpore" (xli. 2, 3, 1). The difficulties which have been stated being borne in mind, the definition of Professor Hunter may be accepted as being at least as good as any other that has been suggested: "Possession is the occupation of anything with the intention of exercising the rights of ownership in respect of it" (*Roman Law*, p. 209). Possession is inchoate or incomplete ownership; it is on its way to become ownership. In the case of the public domain of Rome (*ager publicus*) the possession was really the important matter, the *dominium* being practically of no value. Possession in Roman law was either *natural* or *civil*. The former was mere occupation, the latter such occupation as ripened by prescription into ownership. Possession exclusive against the world (including the true owner) was called "adverse possession." A servitude, such as a right of way, could not be held in true possession, but was said to be in "quasi-possession." The quasi-possessor had, however, possessory remedies.

In Roman law a broad distinction was drawn between possession and ownership (*dominium*).<sup>1</sup> They were protected by different remedies,—possession by interdict, ownership by action. This difference can only be explained by history. Here again, unfortunately, authorities differ. According to Savigny, a Roman citizen who had become a tenant of part of the *ager publicus* could not by any length of holding obtain more than a quasi-ownership, but one of which it would have been morally unjust to have deprived him. "The only legal remedies of which the tenants could avail themselves, if ejected or threatened with disturbance, were the possessory interdicts, summary processes of Roman law which were either expressly devised by the praetor for their protection, or else, according to another theory, had in older times been employed for the provisional maintenance of possessions pending the settlement of questions of legal right" (Maine, *Ancient Law*, ch. viii.). Savigny regards the protection of possession as an extension of the protection of the person. The same view was taken by the English Court of Exchequer in *Rogers v. Spence*, 13 Meeson and Welsby's Reports, 581. According to Professor Hunter (*Roman Law*, pp. 206, 221), Savigny overlooked the needs of aliens. It was the needs of aliens, incapable of the full proprietary rights of Roman citizens, that led to the invention by the praetor of a means of giving them equitable rights in the land, and protecting them in the enjoyment of these rights. Savigny attributes only two rights to possession in Roman law—acquisition of ownership by possession for a given time (*usucapio*, *longi temporis possessio*) and protection of possession from disturbance (*interdictum*). Others have included further rights,—*inter alia*, the right to use force in defence of possession, and the right to have the burden of proof, in a contest as to the title, thrown upon the adversary: "In pari causa possessor potior haberi debet." The position of the possessor in Roman law was a very strong one. If a *bona fide* possessor, he could bring an action for *furtum* even against the owner; if a *mala fide* possessor of land, he was so far protected that he could not be ejected by force. A *mala fide* possessor of movables could, however, acquire no rights.<sup>2</sup>

It has been already stated that there is both a physical and a mental element in the conception of possession. This does not necessarily mean that corporal contact is in all cases requisite, or that the intention to hold the thing possessed as one's own may not be abandoned for a time. The control may be potential as well as actual. An estate may be possessed without the possessor going upon the land at all, and the possession of goods may be given by delivering the key of the warehouse in which they are stored. In international law the possession of part as giving the right to the whole has been of great importance. The possession of the coast of a newly-discovered country gives a right to the inland territory within certain limits (see Twiss, *International Law*, vol. i. p. 170). Where goods are pledged or bailed for a specific purpose the intention of the pledgor or bailor to hold them as his own is suspended during the existence of the limited right of the pledgee or bailee, to whom a fragment of the possession has passed. In Roman law the pledgor had *possessio ad usucapionem*, the pledgee *possessio ad interdicta*. The possession of the pledgee or bailee has been called "derivative possession." Possession may be exercised through another ("animo nostro, corpore alieno"), as through a

servant, who has not true possession.<sup>3</sup> Possession so exercised has been called "representative possession." As soon as the representative determines to assume control on his own behalf or to submit to the control of another, the possession of the principal is gone. Possession may be transferred or lost. It is lost when either the *corpus* or the *animus* (to use the terms of Roman law) ceases to exist. It may be lost by the representative in cases where the principal might have lost it.

In both Roman and English law the possessory tended to supersede the proprietary remedies from their greater convenience,—that is to say, the plaintiff based his claim on the defendant's right upon possession rather than property. The English possessory action may have been directly suggested by the interdict. Bracton (103b) identifies the assise of novel disseisin, the most common form of possessory action, with the interdict *unde vi*. In England ejectment had practically superseded other real actions before the latter were (with the exception of dower, writ of dower, and *quare impedit*) expressly abolished by 3 and 4 Will. IV. c. 27, s. 36. The action for the recovery of land, introduced by the Judicature Acts, is the modern representative of the action of ejectment. The right of a party to recover possession is enforced by a writ of possession.

Possession gives in English law, speaking generally, much the same rights as in Roman law. Thus it serves to found a title (see LIMITATION, PRESCRIPTION), and to throw the onus of proof upon the claimant. In an action for the recovery of land the defendant need only allege that he is in possession by himself or his tenant, and (where such an allegation is necessary) that he had no notice to quit. The chief differences between Roman and English law, arising to some extent from the differences in the history of the two systems, are that the former did not give to derivative possessors (except in the case of pledge) the remedies of possessors, as does English law, and that Roman law is stricter than English in requiring that possession to found *usucapio* should (except in the case of *jus aquæ ducendæ*) be *ex justo titulo*, or under colour of right (see PRESCRIPTION). There is one case of constructive possession which is peculiar to English law,—that is, where possession is said to be given by a deed operating under the Statute of Uses (see "Orme's Case," *Law Reports*, 8 Common Pleas, 281).

In English law the doctrine of possession becomes practically important in the following cases. (1) Possession serves as a convenient means of division of estates (see REAL ESTATE). One of the divisions of estates is into estates in possession and estates in reversion or remainder. It also serves as a division of PERSONAL ESTATE (*q.v.*). A chose in action is said to be reduced into possession when the right of recovery by legal proceedings has become a right of enjoyment. (2) Possession gives a title against a wrongdoer. In the case of real property it is regarded as *prima facie* evidence of seisin.<sup>4</sup> In the case of personal property the mere possession of a finder is sufficient to enable him to maintain an action of trover against one who deprives him of the chattel<sup>5</sup> (see the leading case of *Armory v. Delamirie*, 1 Strange's Reports, 504). (3) What is called "unity of possession" is one of the means whereby an easement is extinguished. Thus the owner of close A may have had a right of way over close B, while the latter belonged to a different owner. If the two closes come to be owned

<sup>3</sup> Much of the law of master and servant is based upon the Roman law of master and slave. The servant, like the slave, has not possession of his master's goods even though they are in his custody, unless, indeed, the circumstances are such that he ceases to be a servant and becomes a bailee.

<sup>4</sup> "Seisin" and "possession" are used sometimes as synonyms, as generally by Bracton; at other times they are distinguished: thus there can be possession of a term of years, but no seisin (Noy, *Maxims*, p. 2). It seems doubtful, however, how far in English law a tenant for years has true possession, for he is in law only a bailiff or servant of the landlord. But he certainly has possessory remedies, like the quasi-possessor in Roman law.

<sup>5</sup> Compare the *Code Napoléon*, art. 2279: "En fait de meubles la possession vaut titre."

<sup>1</sup> The distinction is very important, as it affects the contract of sale. The contract was not to transfer ownership, as in English law, but only *vacua possessio*.

<sup>2</sup> This does not agree with English law, where in certain cases a thief can give a good title to stolen goods, though he has no title himself.

by the same person, the right of way is extinguished, but may under certain circumstances revive on the separation of the ownership. (4) Possession is very important as an element in determining the title to goods under 13 Eliz. c. 5, the Bills of Sale Act, 1878 (41 and 42 Vict. c. 31, ss. 4, 8), and the Bankruptcy Act, 1883 (46 and 47 Vict. c. 52, s. 44). It may be said that as a general rule retention of possession by the transferor on an absolute assignment or a colourable delivery of possession to the transferee is strong *prima facie* evidence of fraud. "Apparent possession" is defined by section 4 of the Bills of Sale Act. (5) Possession of goods or documents of title to goods is generally sufficient to enable agents and others to give a good title under the Factors' Acts (see FACTORS). (6) In criminal law the question of possession is important in founding the distinction between larceny and embezzlement. If the goods are in the possession of the master and he gives them to the custody of his servant for a specific purpose, and the servant steals them, it is larceny; if they have never come into the master's possession, as if a clerk receives money on his master's behalf, it is embezzlement. Recent possession of stolen goods is always regarded as a presumption that the person in whose possession they are stole them or received them knowing them to have been stolen. In the case of a charge of receiving stolen goods evidence may be given that there was found in the possession of the accused other property stolen within the preceding period of twelve months, 34 and 35 Vict. c. 112, s. 19. (For possession in criminal law, see Stephen, *Digest of the Criminal Law*, note xi.). (7) Actions of possession of ships fall within the jurisdiction of the Admiralty Division. This jurisdiction in the case of British vessels depends upon the Admiralty Court Act, 1861 (24 Vict. c. 10, s. 8), in the case of foreign vessels (in which the jurisdiction is rarely exercised) upon the general powers of the court as a maritime court.

The doctrines of adverse possession (in the old English sense, which was not identical with the Roman law, for the real owner must have actually or by fiction been dispossessed) and of *possessio fratris*

are now of only antiquarian interest. The Statutes of Limitation, 3 and 4 Will. IV. c. 27 and 37 and 38 Vict. c. 57, have superseded the first. The only question now is, not whether possession has been adverse or not, but whether twelve years have elapsed since the right accrued (see LIMITATION). The maxim "*possessio fratris de feodo simplici sororem facit esse heredem*" (Coke upon Littleton, 14b) has been altered by the rules of descent introduced by 3 and 4 Will. IV. c. 106, under which descent is traced from the purchaser. At one time possessory suits were occasionally maintained in England, and more frequently in Ireland, for the quieting of possession after proof of three years' possession before the filing of the bill. But such suits are now obsolete (see Neill v. Duke of Devonshire, 8 *Appeal Cases*, 146). There was one characteristic case in old English law in which possession was maintained by means of what was called "continual claim," made yearly in due form, where the person having the right was prevented by force or fear from exercising it (Coke upon Littleton, 253b). Continual claim was abolished by 3 and 4 Will. IV. c. 27, s. 11.

*Scotland*.—In Scotland possessory actions still exist *eo nomine*. Actions of molestation, of removing, and of mails and duties are examples. A possessory judgment is one which entitles a person who has been in possession under a written title for seven years to continue his possession (Watson, *Law Dict.*, s.v. "Possessory Judgment").

*United States*.—Here the law in general agrees with that of England. But in Maryland, New Hampshire, North Carolina, and Vermont the doctrine of *possessio fratris* apparently still exists (Bouvier, *Law Dict.*, "*Possessio Fratris*"). Possessory rights are taxed in some of the States. Louisiana follows Roman law closely. Possession of incorporeal rights (to use the unscientific language of the Code) is called quasi-possession, and the division of possession into natural and civil is maintained (Civil Code, §§ 3389-3419).

In addition to the authorities cited may be mentioned Smith, *Dict. of Antiquities*, s.v. "*Possessio*"; Markby, *Elements of Law*, ch. viii.; Holland, *Elements of Jurisprudence*, ch. xi.; Holmes, *The Common Law* (lect. vi.). (J. Wt.)

## POST-OFFICE

THE germ of the modern postal systems of the world is to be looked for, obviously, in the earliest organized establishment of a staff of Government couriers. When, or under what precise circumstances, such an establishment was first made available by a state for the carriage of the letters of private persons there is no satisfactory evidence to show. That there must have been, even in early times, a connexion, more or less authorized, between the transmission of public and of private correspondence is highly probable. Even financial reasons would soon dictate a formal permission to Government couriers to carry letters for individuals—under regulation and restriction, of course—although at the outset such a practice may well have been rather connived at than allowed. In the postal system of Spain and the German empire there is express record of such a permission in the month of April 1544; and within fifteen or sixteen years that permission had grown into a legalized and regulated monopoly, whence the counts of Taxis drew part of their profits as postmasters-general. For the purposes of this article, however, it is enough to note that in Great Britain existing private letters of the 15th century—some, perhaps, of the 14th—bear endorsements which show that they were conveyed by relays of men and horses maintained under the control of the Government, and primarily intended for its special service. In several Continental states the universities had inland postal establishments of a rudimentary sort at an early date. The university of Paris, for example, organized a postal service almost at the beginning of the 13th century, and it lasted in a measure until the year 1719. In various parts of Europe mercantile guilds and brotherhoods were licensed to establish posts for commercial purposes. But everywhere—as far as the accessible evidence extends—foreign posts were under state control.

### GREAT BRITAIN.

#### *Early History (c. 1533-1836).*

As early as the middle of the 13th century entries

occur in the wardrobe accounts of the kings of England of payments to royal messengers—variously designated "*cokinus*," "*nuncius*," or "*garcio*"—for the conveyance of letters to various parts of the country. In the supervision of these royal messengers lies the germ of the office of postmaster-general. The first English postmaster of whom a distinct account can be given is Sir Brian Tuke, <sup>teenth century.</sup> who is described (1533) in the records as "*Magister Nunciorum, Cursorum, sive Postarum*," "*both in England and in other parts of the king's dominions beyond the seas*." But long subsequent to this appointment of a postmaster-general the details of the service were frequently regulated by proclamations and by orders in council. Thus, in the curious collection of royal proclamations in the library of the Society of Antiquaries there is one of Philip and Mary (undated, but apparently of 1555) which regulates the supply of horses for the conveyance of letters to Dover.<sup>1</sup> Again, in July 1556 the lords of the council ordered "that the postes betweene this and the Northe should eche of them keepe a booke, and make entrie of every lettre that he shall receive, the tyme of the deliverie thereof unto his hands, with the parties names that shall bring it unto him." Much of the business of the foreign postal service to and from England during the earlier years of Queen Elizabeth was managed by the incorporated "merchant strangers," who appointed a special postmaster amongst themselves. When that office chanced to fall vacant in 1568 they quarrelled about a successor; and the quarrel cost them their privilege.<sup>2</sup>

The accession of James I. to the English throne, by necessitating a more frequent communication between James I. London and Scotland, led to improvements in the postal

<sup>1</sup> In his able account of this remarkable collection the late Mr Robert Lemon has overlooked the proclamation here referred to, probably from its want of a date, his own arrangement being chronological.

<sup>2</sup> F. Windebank to Sir W. Cecil: "All the Italians were unwilling to give their voices to Raphael, . . . but inclined to favour Godfrey" (*Dom. Cor. Eliz.*, xlviii. § 65, State Paper Office). Raphael was a German, Godfrey an Englishman.

service. Some years earlier special posts had been established by the magistrates of certain Scottish towns for the conveyance of their despatches to and from the court. Thus in 1590 a messenger was appointed by the magistrates of Aberdeen with the title of "council-post."<sup>1</sup> The new royal orders of 1603 directed (1) that the postmasters at the various stages should enjoy the privilege of letting horses to "those riding in post (that is to say) with horn and guide," by commission or otherwise, and to that end they were charged to keep or have in readiness a sufficient number of post-horses; (2) that the lawful charge for the hire of each horse should be, for public messengers, at the rate of 2½d. a mile, "besides the guides' groats," private travellers being left to make their own agreements. Finally, it was directed that every postmaster should keep at least two horses for the express conveyance of Government letters, and should forward such letters within a quarter of an hour of their receipt, and that the posts should travel at the rate of not less than 7 miles an hour in summer and 5 miles in winter.<sup>2</sup>

In 1607 the king granted to James Stanhope, first Lord Stanhope of Harrington, and to his son Charles Stanhope, afterwards second Lord Stanhope, jointly and to the survivor of them, the postmastership of England under the title of "Master of the Posts and Messengers," with a fee of 100 marks a year, together with all "avails and profits" belonging to the office. In 1619 a separate office of "postmaster-general of England for foreign parts" was created, by new letters patent, in favour of Matthew de Quester<sup>3</sup> and Matthew de Quester the younger. The new office was regarded by the existing postmaster-general, Charles, Lord Stanhope, as an infringement of his own patent. A long dispute ensued in the King's Bench and before the Lords of the Council.<sup>4</sup> In 1626 by an order in council liberty was granted to all companies of merchants, including the Merchants Adventurers, to send their letters and despatches by messengers of their own choosing. A year afterwards this liberty was revoked, except for the Company of Merchants Adventurers. Lord Stanhope, however, continued to carry letters abroad by his agents, and obtained a warrant prohibiting De Quester from interfering. It shows strikingly the confusion of postal affairs at this period to find a statement addressed to the privy council by the postmasters of England to the effect that they had received no payments "ever since the last day of November 1621 till this present time, June 1628,"—the arrears amounting to £22,626.

The rights of the postmasters were also infringed by private individuals, as by one Samuel Jude in 1629 in the west of England.<sup>5</sup> In 1632 the foreign postmastership was assigned by the De Questers to William Frizell and

Thomas Witherings. Letters-patent were granted to them Witherings jointly, 15th March 1633.<sup>6</sup> Witherings took the labouring oar, and probably ought to rank as the first of the many conspicuous postal reformers in the long history of the British post-office. Under him one Richard Poole obtained a special postmastership for the service of the court. A petition subsequently presented by him to the House of Lords contains curious proof of the jealousies which Witherings's successful administration of his office excited. Among the earliest measures of improvement taken under the new patent was an acceleration of the Continental mail service. For this purpose the patentees made a contract with the count of Thurn and Taxis, hereditary postmaster of the empire and of Spain. At this time there was still but one mail weekly between London, Antwerp, and Brussels, and the transit occupied from four to five days. By a subsequent contract with Count Thurn two mails weekly were secured and the transit made ordinarily in two days.<sup>7</sup> In June 1635 Witherings submitted to the king a proposal (still preserved in the State-Paper Office) "for settling of staffets or packet-posts betwixt London and all parts of His Majesty's dominions, for the carrying and re-carrying of his subjects' letters," which contains some curious incidental notices of the state of the internal communication of the kingdom at that time. The nett charge to the crown of the existing posts is stated to be £3400 per annum. Letters, it is said, "being now carried by carriers or footposts 16 or 18 miles a day, it is full two months before any answer can be received from Scotland or Ireland to London. If any of His Majesty's subjects shall write to Madrid in Spain, he shall receive answer sooner and surer than he shall out of Scotland or Ireland." By the new plan it was proposed that all letters for the northern road should be put into one "portmantle," and directed to Edinburgh, with separate bags directed to such postmasters as lived upon the road near to any city or town corporate. The journey from London to Edinburgh was to be performed within three days. The scheme was approved of on 31st July 1635, the proclamation establishing eight main postal lines,—namely, the great northern road, to Ireland by Holyhead, to Ireland by Bristol, to the marches of Wales by Shrewsbury, to Plymouth, to Dover, to Harwich, and to Yarmouth. The postage of a single letter was fixed at 2d. if under 80 miles, 4d. if between 80 and 140 miles, 6d. if above 140 miles, 8d. if to Scotland. And it was further provided that from the beginning of this service no other messengers or footposts should carry letters to any places so provided, except common known carriers, or a particular messenger "sent on purpose with a letter by any man for his own occasions," or a letter by a friend, on pain of exemplary punishment.<sup>8</sup> In February 1638 another royal proclamation ratified an agreement between Witherings and De Noveau, postmaster to the French king, for the conveyance of the mails into France by Calais, Boulogne, Abbeville, and Amiens.<sup>9</sup>

But in 1640 the active postmaster was accused of divers abuses and misdemeanours, and his office sequestered into the hands of Philip Burlamachi of London, merchant, who was to execute the same under the inspection of the principal secretary of state.<sup>10</sup> Witherings then assigned his patent to Robert Rich, earl of Warwick, and a long contest

<sup>3</sup> Or "De l'Equester," as he is called in Latch's *Reports of King's Bench Cases*, p. 87.

<sup>4</sup> These disputes were much embittered by the growing jealousies of English against foreign merchants. The proofs of this in the state correspondence of Elizabeth's day are abundant, but there were many statesmen who took larger views. See, e.g., John Johnson's "Brief Declaration for the . . . erecting and maintaining of the Staple . . . in England" (June 1582), *Dom. Corresp. Eliz.*, cliv., No. 30; and compare the same writer's "Discourse for the repairing the decayed State of the Merchants," &c. (22d July 1577), *ib.*, cxiv., No. 39, with Leake's "Discourse," &c., of the same year (*ib.*, cxi. 1 sq.), and with John Hales's "Letter to Sir W. Cecil" (20th March 1559), *ib.*, iii., where he describes the merchant strangers as being "spies for foreign princes," and with Cecil's "Reasons to move a Forbearing of the Restitution of the Intercourse to Antwerp" (1564), *ib.*, xxv., No. 33 (in Rolls House).

ensued in both Houses of Parliament. The sequestration was declared by a vote in parliament in 1642 to be illegal. Nevertheless the dispute gave repeated occupation to both Houses during the period from 1641 to 1647, and was diversified by several affrays, in which violent hands were laid upon the mails. In 1643 the post-office yielded only £5000 a year. In 1644 the Lords and Commons by a joint ordinance appointed Edmund Prideaux "to be master of the posts, messengers, and couriers." In 1646 the opinion of the judges was taken on the validity of Witherings's patent (assigned to Lord Warwick), and they pronounced that "the clauses of restraint in the said patent are void and not good in law; that, notwithstanding these clauses be void, the patent is good for the rest."<sup>1</sup> It is evident, therefore, that any prohibition to carry letters must be by Act of Parliament, to have force of law.

In 1650 an attempt was made by the common council of London to organize a new postal system on the great roads, to run twice a week. This scheme they temporarily carried into effect as respects Scotland. But Mr Attorney-General Prideaux speedily obtained the intervention of the council of state. He urged on the council of state that, if the new enterprise were permitted, besides intrenching on the rights of the parliament, some other means would have to be devised for payment of the postmasters. Both Houses resolved (1) that the offices of postmasters, inland and foreign, were, and ought to be, in the sole power and disposal of the parliament, and (2) that it should be referred to the council of state to take into consideration all existing claims in relation thereto. Of these there were no less than five under the various patents which had been granted and assigned. Thereupon the Protector was advised that the management of the post-office should be entrusted to John Thurloe by patent under the broad seal of the Commonwealth immediately upon the expiration of John Manley's existing contract. Thurloe was to give security for payment of the existing rent of £10,000 a year. Ultimately the posts, both inland and foreign, were farmed to John Manley for £10,000 a year, by an agreement made in 1653. Meanwhile, and pending the decision of the council upon the question so submitted to it, a remarkable step in postal reform was taken by an attorney at York, named John Hill, who placed relays of post-horses between that city and London, and undertook the conveyance of letters and parcels at half the former rates of charge. He also formed local and limited partnerships in various parts of the kingdom for the extension of his plan, which aimed to establish eventually a general penny postage for England, a twopenny postage for Scotland, and a fourpenny postage for Ireland. But the post-office was looked upon by the Government of the day as, first, a means of revenue, and secondly, a means of political espionage.<sup>2</sup> The new letter-carriers were

(literally) "trampled down" by Cromwell's soldiery. The inventor had a narrow escape from severe punishment. He lived to publish (1659) the details of his plan, at the eve of the Restoration, in a pamphlet entitled *A Penny Post: or a Vindication of the Liberty and Birthright of every Englishman in carrying Merchants and other Men's letters, against any Restraint of Farmers, &c.* It is very probable that this publication<sup>3</sup> helped to prepare the way for those measures of partial but valuable and far-reaching reform which were effected during the reign of Charles II. The rates of postage and the rights and duties of postmasters were settled under the Protectorate by an Act of Parliament of 1657, c. 30. In 1659 the item, "by postage of letters in farm, £14,000," appears in a report on the public revenue.<sup>4</sup>

The Government of the Restoration continued to farm the post-office upon conditions very similar to those imposed by the Act of 1657, but for a larger sum. Henry Bishop was the first postmaster-general in the reign of Charles II., and he contracted to pay to the king a yearly rent of £21,500, these new arrangements being embodied in the Act 12 Charles II. c. 35, entitled "An Act for Erecting and Establishing a Post-Office." A clause proposing to frank all letters addressed to or sent by members of parliament during the session was, after considerable debate, ultimately rejected by the Lords. But the indenture enrolled with the letters-patent contained a proviso for the free carriage of all letters to or from the king, the great officers of state, and also the single inland letters only of the members of that present parliament during the continuance of that session. It also provided that the lessee should permit the secretaries of state for the time being, or either of them, from time to time, to have the survey and inspection of all letters at their discretion. Bishop was succeeded by Daniel O'Neill<sup>5</sup> in 1662, on similar terms. In the consequent proclamation, issued on 25th May 1663, it was commanded that "no postmasters or other officers that shall be employed in the conveying of letters, or distributing of the same, or any other person or persons, . . . except by the immediate warrant of our principal secretaries of state, shall presume to open any letters or packets not directed unto themselves." In 1677 the general post-office comprised in the chief office, under Henry Bennet, earl of Arlington, as postmaster-general, seventy-five persons, and its profits were farmed for £43,000 a year. There were then throughout England and Scotland 182 deputy postmasters, and in Ireland 18 officers at the Dublin office and 45 country postmasters. "The number of letters missive," says a writer of the same year, "is now prodigiously great. . . . A letter comprising one whole sheet of paper is conveyed 80 miles for twopence. Every twenty-four hours the post goes 120 miles, and in five days an answer may be had from a place 300 miles distant."<sup>6</sup>

By an Act of the 15th Charles II. ("An Act for Settling the Profits of the Post-Office on H.R.H. the Duke of York, and his Heirs-Male"), and by a subsequent proclamation issued in August 1683, it was directed that the postmaster-general should "take effectual care for the conveyance of all bye-letters, by establishing correspondences . . . in all considerable market-towns with the next adjacent post-stage," and the rights of the postmasters as to hiring horses were again emphasized.

<sup>1</sup> *Journals of the House of Commons*, ii. 81, 82, 95, 470, 493, 500, 501, 658 sq.; *Journals of the House of Lords*, v. 343, 387, 450, 469, 473, 500 sq.; *Report from Secret Committee on the Post-Office*, Appendix, 60-69.

<sup>2</sup> Some instructive illustrations of this may be seen (in the state-paper department of the General Record Office) among the correspondence between secretary Sir John Coke and Lord Conway, and also in many other state letters, as well after the outbreak of the great rebellion as before it. And there is in the Bodleian Library at Oxford (MS. Rawlinson, A. 477) a curiously minute account of the methods alleged to have been pursued in the systematic and periodical examination of letters entrusted to the post-office. The paper is not authenticated by any signature, and is undated. But it is an original document of the time of Charles II., addressed to Mr Bridgman, clerk of the council, and drawn up in order to recommend the adoption of a like practice, but with greater dexterity in the manipulation than was used by Dr Dorislaus and Samuel Morland, who, according to this narrative, formed the Cromwellian board of examiners for post-office letters, and who read without exception all that were addressed to foreign parts.

<sup>3</sup> There is a copy in the library of the British Museum, from which Mr H. B. Wheatley has given the abstract quoted above.

Dock-  
wra's  
London  
penny  
post.

It was during the possession of the post-office profits by the duke of York that a London penny post was established by the joint enterprise of William Dockwra, a searcher at the customs house, and of Robert Murray, a clerk in the excise office. The working-out of the plan fell to the first-named, and in his hands it gave in April 1680—although but for a short time—far more extensive postal facilities to the Londoners than even those so memorably afforded 160 years later by the plans of Sir Rowland Hill. The London of that day was small, and easily manageable. Dockwra carried, registered, and insured, for a penny, both letters and parcels up to a pound in weight and £10 in value. He took what had been the mansion of Sir Robert Abdy in Lime Street as a chief office, established seven sorting and district offices (thus anticipating one of the most recent improvements of the present time) and between 400 and 500 receiving-houses and wall-boxes. He established hourly collections, with a maximum of ten deliveries daily for the central part of the city, and a minimum of six for the suburbs. Outlying villages, such as Hackney and Islington, had four daily deliveries; and his letter-carriers collected for each despatch of the general post-office throughout the whole of the city and suburbs. Suits were laid against him in the court of King's Bench for infringing on the duke of York's patent, and the jealousies of the farmers eventually prevailed. The penny post was made a branch of the general post. Dockwra, after the Revolution of 1688, obtained a pension of £500 a year (for a limited term) in compensation of his losses. In 1697 he was made comptroller of the London office. Eleven years later his improvements were outwied by Charles Povey, the author of schemes for improving coinage, and also of a very curious volume, often wrongly ascribed to Defoe, entitled *The Visions of Sir Heister Ryley*. Povey took upon himself to set up a foot-post under the name of the "halfpenny carriage," appointed receiving-houses, and employed several persons to collect and deliver letters for hire within the cities of London and Westminster and borough of Southwark, "to the great prejudice of the revenue," as was represented by the postmaster-general to the lords of the treasury. Povey was compelled to desist.

Early  
Scottish  
postal  
system.

At this period the postal system of Scotland was distinct from that of England. It had been reorganized early in the reign of Charles II., who in September 1662 had appointed Patrick Grahame of Inchbrakie to be postmaster-general of Scotland for life at a salary of £500 Scots. But it would seem from the proceedings of the Scottish privy council that the rights and duties of the office were ill defined; for immediately after the appointment of Grahame the council commissioned Robert Mein, merchant and keeper of the letter-office in Edinburgh, to establish posts between Scotland and Ireland, ordained that Linlithgow, Killyth, Glasgow, Kilmarnock, Dumboag, Ballantrae, and Portpatrick should be stages on the route, and granted him the sum of £200 sterling to build a packet-boat to carry the mail from Portpatrick to Donaghadee.<sup>1</sup>

Early  
colonial  
posts.

The colonial post-office at this period was naturally more rudimentary still. Perhaps the earliest official notice of it is to be seen in the following paragraph from the records of the general court of Massachusetts in 1639. "It is ordered that notice be given that Richard Fairbanks his house in Boston is the place appointed for all letters which are brought from beyond the seas, or are to be sent thither to be left with him; and he is to take care that they are to be delivered or sent according to the directions; and he is allowed for every letter a penny, and must answer all miscarriages through his own neglect in this kind." That court in 1687 was petitioned to make better postal arrangements, the petitioners alleging the frequent "loss of letters whereby merchants, especially with their friends and employers in foreign parts, are greatly damaged; many times the letters are imputed (!) and thrown upon the Exchange, so that those who will may take them up, no person, without some satisfaction, being willing to trouble their houses therewith." In Virginia the postal system was yet more primitive. The colonial law of 1657 required every planter to provide a messenger to convey the despatches as they arrived to the next plantation, and so on, on pain of forfeiting a hogshead of tobacco in default.

<sup>1</sup> Lang, *Historical Summary of the Post-Office in Scotland*, 4, 5.

The Government of New York in 1672 established "a post to goe monthly from New York to Boston," advertising "those that bee disposed to send letters, to bring them to the secretary's office, where, in a lockt box, they shall be preserved till the messenger calls for them, all persons paying the post before the bagg be sealed up." Thirty years later this monthly post had become a fortnightly one, as we see by the following paragraph in the *Boston News-Letter*. "By order of the postmaster-general of North America. These are to give notice, That on Monday night, the 6th of December, the Western Post between Boston and New York sets out once a fortnight, the three winter months of December, January, and February, and to go alternately from Boston to Saybrook, and Hartford, to exchange the mayle of letters with the New York Ryder; the first turn for Saybrook, to meet the New York Ryder on Saturday night the 11th current; and the second turn he sets out at Boston on Monday night the 20th current, to meet the New York Ryder at Hartford, on Saturday night the 25th current, to exchange Mayles; and all persons that sends letters from Boston to Connecticut from and after the 13th inst. are hereby notified first to pay the Postage on the same." This office of postmaster-general for America had been created in 1692.

We have now traced the postal communications of different portions of the British empire from their earliest beginnings until the eve of the passing of the Act of the 9th of Queen Anne which consolidated them into one establishment, and which, as to organization, continued to be the great charter of the post-office until the date of the important reforms of 1838-50, mainly introduced by the energy, skill, and characteristic pertinacity of Sir Rowland Hill. The Act of Anne largely increased the powers of the postmaster-general. It reorganized the chief letter-offices of Edinburgh, Dublin, and New York, and settled new offices in the West Indies and elsewhere. It established three rates of single postage, viz., English, 3d. if under 80 miles and 4d. if above, and 6d. to Edinburgh or Dublin. It continued to the postmaster-general the sole privilege "to provide horses to persons riding post." And it gave, for the first time, parliamentary sanction to the power, formerly questionable, of the secretaries of state with respect to the opening of letters, by enacting that "from and after the first day of June 1711 no person or persons shall presume . . . to open, detain, or delay . . . any letter or letters . . . after the same is or shall be delivered into the general or other post-office, . . . and before delivery to the persons to whom they are directed, or for their use, except by an express warrant in writing under the hand of one of the principal secretaries of state, for every such opening, detaining, or delaying."

Nine years after the passing of the Act of Anne the Cross-cross-roads were farmed to the well-known "humble" road Ralph Allen,—the lover of peace and of humanity.<sup>2</sup> Allen became the inventor of the cross-roads postal system, having made an agreement that the new profits so created should be his own during his lifetime. His improvements were so successful that he is said to have netted during forty-two years an average profit of nearly £12,000 a year. The postal revenue of Great Britain, meanwhile, stood thus:—

TABLE I.—Gross and Nett Income, 1724-1774.

	Gross Produce.			Nett Revenue.		
	£	s.	d.	£	s.	d.
1724	178,071	16	9	96,339	7	5
1734	176,334	3	1	91,701	11	0
1744	194,461	8	7	85,114	9	4
1754	214,300	10	6	97,365	5	1

1774	313,032	14	6	164,077	8	4

<sup>2</sup> Miles, "History of the Post-Office," in the *American Banker's Magazine*, n. s., vii, 358 *et seq.*

<sup>3</sup> Buckingham, *Specimens of Newspaper Literature* (Boston, 1850), i, 16, 17.

<sup>4</sup> "Is there a variance? enter but his door,  
Balked are the courts; the contest is no more."  
Pope's "humble Allen" was also the "Allworthy" of Fielding.

The system of burdening the post-office revenue with pensions, nearly all of which had not the slightest connexion with the postal service, and some of which were unconnected with any sort of service that can possibly be called public, was begun by Charles II., who granted to Barbara, duchess of Cleveland, £4700 a year, and to the earl of Rochester £4000 a year, out of that revenue. The example was followed until, in 1694, the list of pensions so chargeable stood thus:—

Earl of Rochester.....	£4,000	Lord Keeper.....	£2,000
Duchess of Cleveland.....	4,700	William Dockwra (until 1697).....	500
Duke of Leeds.....	3,600		
Duke of Schomberg.....	4,000	Total.....	£21,200
Earl of Bath.....	2,500		

Queen Anne granted a pension of £5000 to the duke of Marlborough, charged in like manner. In March 1857 the existing pensions ceased to be payable by the post-office, and became chargeable to the consolidated fund.

The first important and enduring impulse to the development of the latent powers of the post-office, both as a public agency and as a source of revenue, was given by the shrewdness and energy of the manager of the Bath theatre, John Palmer. Palmer's notice was attracted to the subject in October 1782. His avocations had made him familiar with that great western road which was still in such peculiar favour, alike with people of fashion and with the gentlemen of the highway. So habitual were the robberies of the post that they came to be regarded by its officials as among the necessary conditions of human affairs. They urged on the public the precaution of sending all bank-notes and bills of exchange in halves, and pointed the warning with a philosophical remark, that "*there are no other means of preventing robberies with effect*, as it has been proved that the strongest carts that could be made, lined and bound with iron, were soon broken open by a robber."

At this period, in addition to the recognized perils of the roads, the postal system was characterized by extreme irregularity in the departure of mails and delivery of letters, by an average speed of about  $3\frac{1}{2}$  miles in the hour, and by a rapidly-increasing diversion of correspondence into illicit channels. The nett revenue, which had averaged £167,176 during the ten years ending with 1773, averaged but £159,625 during the ten years ending with 1783. Yet, when Palmer suggested that by building mail-coaches of a construction expressly adapted to run at a good speed, by furnishing a liberal supply of horses, and by attaching an armed guard to each coach the public would be greatly benefited, and the post-office revenue considerably increased, the officials pertinaciously opposed the plan and maintained that the existing system was all but perfect. Lord Camden, however, brought the plan under the personal notice of Pitt. No sooner was the minister convinced of its merits than he insisted on its being tried. The experiment was made in August 1784, and its success exceeded all anticipation. The following table will show the rapid progress of the postal revenue under the new arrangements.

TABLE II.—Gross and Nett Income, 1784-1805.

Year.	Gross Income.			Nett Revenue.		
	£	s.	d.	£	s.	d.
1784.....	420,101	1	8	196,513	16	7
1785.....	463,753	8	4	261,409	18	2
1790.....	533,198	1	9	331,179	18	8
1795.....	745,238	0	0	414,548	11	7
1800.....	1,083,950	0	0	720,981	17	1
1805.....	1,317,842	0	0	944,332	8	4

It had been at first proposed to reward Palmer by a grant for life of two and a half per cent. on a certain proportion of the increased nett revenue, which would eventually have given him some £10,000 a year; but this proposition fell through, in consequence either of technical difficulties created by the Post-Office Act or of the opposition of the post-office authorities. Pitt, how-

ever, appointed Palmer to be comptroller-general of postal revenues, an office which was soon made too hot for him to hold. He obtained a pension of £3000 a year, and ultimately, by the Act 53 Geo. III. c. 157, after his case had received the sanction of five successive majorities against Government, an additional sum of £50,000. Every sort of obstruction was placed in the way of his reward, although nearly a million had been added to the annual public revenue, and during a quarter of a century the mails had been conveyed over an aggregate of some seventy millions of miles without the occurrence of one serious mail robbery.<sup>1</sup>

Scotland shared in the advantages of the mail-coach system from Scottish the first. Shortly before its introduction the local penny post was and Irish set on foot in Edinburgh by Peter Williamson, the keeper of a post-coffee-room in the hall of Parliament House. He employed four office letter-carriers, in uniform, appointed receivers in various parts of 1708 the city, and established hourly deliveries.<sup>2</sup> The officials of the 1801 post, when the success of the plan had become fully apparent, gave Williamson a pension, and absorbed his business, the acquisition of which was subsequently confirmed by the Act 31 Geo. III. c. 17. A dead-letter office was established in 1784. The entire staff of the Edinburgh post-office, which consisted in 1708 of seven persons, now comprised twenty-five, the cost of the office being £1406. In 1796 the number of functionaries had increased to forty, and the cost to £3278.<sup>3</sup> But in Ireland the old state of things continued until the present century. In 1801 only three public carriages in the whole country conveyed mails. There were, indeed, few roads of any sort, and none on which coaches could travel faster than four miles an hour.<sup>4</sup> At this period the gross receipts of the Irish post-office were £30,010; the charges of management and collection were £59,216, or at the rate of more than 70 per cent.; whilst in Scotland the receipts were £100,651, and the charges £16,896, or somewhat less than 17 per cent.<sup>5</sup>

In the American colonies postal improvements may be dated from Franklin's administration of Franklin, who was virtually the last colonial lin. postmaster-general, as well as unquestionably the best. In one shape or another he had forty years' experience of postal work, having been appointed postmaster at Philadelphia as early as October 1737. When he became postmaster-general in 1753 he bestirred himself for the improvement of his department in that practical painstaking way with which he was wont to guide any plough he had once put his hand to, whatever the ground it had to work in. He visited all the chief post-offices throughout Pennsylvania, New Jersey, New York, and New England, looking at everything with his own eyes. His administration cannot be better summed up than we find it to be in a sentence or two which he wrote soon after his dismissal. Up to the date of his appointment, he says, "the American post-office had never paid anything to that of Britain. We [i.e., himself and his assistant] were to have £600 a year between us, if we could make that sum out of the profits of the office. . . . In the first four years the office became above £900 in debt to us. But it soon after began to repay us; and before I was displaced by a freak of the minister's, we had brought it to yield three times as much clear revenue to the crown as the post-office of Ireland. Since that imprudent transaction they have received from it—not one farthing."

The interval between the development of Palmer's improved methods (as far as that development was permitted by the authorities), which we take to be pretty nearly contemporaneous with the parliamentary settlement of his claims, and the still more important reforms introduced twenty-seven years later by Sir Rowland Hill, is chiefly marked by the growth of the packet-system, under the influence of steam navigation, and by the elaborate investigations of the revenue commissioners of 1826 and the following years. Undoubtedly the inquiries of these commissioners attracted a larger share of public attention to the management of the post-office than had theretofore been bestowed on it; but, if anything had been wanted to throw into bolder relief Hill's intelligent and persevering exertions, these reports supply the want in ample measure. In some important particulars they mark out practical and most valuable reforms, but they are so clumsy in arrangement, so resiliant in the treatment of the various branches of the service, and so crowded with petty details as to contrast most unfavourably with the lucid order and vigorous reasoning of Rowland Hill's *Post-*

<sup>1</sup> *Debates of both Houses of Parliament in 1808 relative to the Agreement for the Reform and Improvement of the Post-Office*, passim.

<sup>5</sup> *Report, &c., of Select Committee on Postage*.

*Office Reform.* While the functionaries of the post-office are criticized with a severity so salient as to wear an appearance at times of almost personal hostility, the truth that a very large and liberal increase of public facilities would be likely to benefit the revenue much more materially than small economies in salaries and perquisites seems scarcely to have dawned on the minds of the commissioners. Even in dealing with a new accommodation actually provided—that of the money-order office—whilst taking just exception to the unofficial character of its management, they incline rather to its abolition than to its reform.

*Packet services.* As early as 1788 the cost of the packets employed by the post-office attracted parliamentary attention. In that year the "commissioners of fees and gratuities" reported that in the preceding seventeen years the total cost of this branch had amounted to £1,038,133; and they naturally laid stress on the circumstance that many officers of the post-office were owners of such packets, even down to the chamber-keeper. At this time part of the packet service was performed by hired vessels, and part by vessels which were the property of the crown. The commissioners recommended that the latter should be sold, and the entire service be provided for by public and competitive tender. The subject was again inquired into by the Finance Committee of 1792, which reported that the recommendation of 1788 had not been fully acted upon, and expressed its concurrence in that recommendation. The plan was then to a considerable extent enforced. But the war rapidly increased the expenditure. The average (£61,000) of 1771-87 had increased in 1797 to £78,400, in 1810 to £103,000, in 1814 to £160,000. In the succeeding years of peace the expenses fell to an average of about £55,000. As early as 1818 the "Bob Roy" plied regularly between Greenwich and Belfast; but no use was made of steam navigation for the postal service until 1821, when the postmaster-general established crown packets. The expenditure under the new system, from that date to 1829 inclusive, was thus reported by the commissioners of revenue in 1830.

TABLE III.—Cost of Packet Service, 1820-1829.<sup>1</sup>

Year.	Year.
1820.....£55,000	1825.....£110,000
1821.....154,000	1826.....110,000
1822.....115,000	1827.....110,000
1823.....115,000	1828.....110,000
1824.....115,000	1829.....110,000

The general administration of postal affairs at this period was still characterized by repeated advances in the letter rates, and the twenty years previous to Rowland Hill's reforms by a stationary revenue. The following table (IV.) will show the gross receipts, the charges of collection and management, and the nett revenue (omitting fractions of a pound) of the post-office of Great Britain. We give the figures for the year 1836 for the purpose of comparison.

Year.	Gross Receipts.	Charges of Collection, &c.	Charges of Management, &c.	Nett Revenue.	Population of United Kingdom.
1836	£1,562,657	£11,411	22	£1,551,224	16,552,000
1816-18	2,143,741	294,672	27	1,848,042	12,552,000
1811-13	2,509,312	714,122	23	1,795,068	11,552,000
1806-21	2,182,235	600,229	22	1,581,784	10,225,000
1801-25	2,235,229	657,914	22	1,577,325	9,225,000
1796-25	2,122,252	717,613	31	1,404,628	8,225,000
1791-25	2,507,706	654,229	27	1,849,248	7,225,000
1786-25	2,212,273	654,763	22	1,552,788	6,225,000

*Governmental interference with correspondence.* Before passing to the reform of 1839 we have to revert to that important feature in postal history,—the interference with correspondence for judicial or political purposes. We have already seen (1) that this assumption had no parliamentary sanction until the enactment of the 9th of Queen Anne; (2) that the enactment differed from the royal proclamations in directing a special warrant for each opening or detention of correspondence. It is a significant gloss on the statute to find that for nearly a century (namely, until 1793 inclusive) it was not the practice to record such warrants regularly in any official book.<sup>4</sup> Of the use to which the power was applied the state trials afford some remarkable instances. At the trial of Bishop Atterbury, for example, in 1723 certain letters were offered in evidence which a clerk of the post-office deposed on oath "to be true copies from the originals, which were stopped at the post-office and copied, and sent forward as directed." Hereupon Atterbury very naturally asked this witness "if he had any express warrant under the hand of one of the principal secretaries of state for opening the said letters." But the Lords shelved his objection and put a stop to his inquiry on the grounds of public inexpediency.

Twenty-nine peers recorded their protest against this decision.<sup>5</sup> But the practice thus sanctioned appears to have been pushed to such lengths as to elicit in April 1735 a strong protest and censure from the House of Commons. In the preceding February complaints were made by several members that not only were their letters charged at the post-office, but they were often broken open and perused by the clerks, that the practice of breaking open letters was become frequent, and was so publicly known that "the liberty given to break open letters . . . could now serve no purpose but to enable the idle clerks about that office to pry into the private affairs of every merchant and of every gentleman in the kingdom."<sup>6</sup> A committee of inquiry was appointed, and after receiving its report the House resolved that it was "an high infringement of the privileges of the . . . Commons of Great Britain in Parliament for any postmaster, his deputies, or agents, in Great Britain or Ireland, to open or look into, by any means whatever, any letter directed to or signed by the proper hand of any member, without an express warrant in writing under the hand of one of the principal secretaries of state for every such opening and looking into; or to detain or delay any letter directed to, or signed with the name of any member, unless there shall be just reason to suspect some counterfeit of it, without an express warrant of a principal secretary of state for every such detaining or delaying."

### Sir Rowland Hill's Reforms (1836-1842).

Rowland Hill's pamphlet (*Post-Office Reform*) of 1837 took for its starting-point the fact that, whereas the postal revenue showed for the past twenty years a positive though slight diminution, it ought to have showed an increase of £507,700 a year in order to have simply kept pace with the growth of population (see Table IV. above), and an increase of nearly four times that amount in order to have kept pace with the growth of the analogous though far less exorbitant duties imposed on stage-coaches. The stage-coach duties had produced in 1815 £217,671; in 1835 they produced £498,497. In 1837 there did not exist any precise account of the number of letters transmitted through the general post-office. Hill, however, was able to prepare a sufficiently approximate estimate from the data of the London district post, and from the sums collected for postage. He thus calculated the number of chargeable letters at about 88,600,000, that of franked letters at 7,400,000, and that of newspapers at 30,000,000, giving a gross total of about 126,000,000. At this period the total cost of management and distribution was £696,569. In the finance accounts of the year (1837) deductions are made from the gross revenue for letters "refused, missent, redirected," and the like, which amount to about £122,000. An analysis of the component parts of this expenditure assigned £426,517 to cost of primary distribution and £270,052 to cost of secondary distribution and miscellaneous charges. A further analysis of the primary distribution expenditure gave £282,308 as the probable outgoings for receipt and delivery and £144,209 as the probable outgoings for transit. In other words, the expenditure which hinged upon the distance the letters had to be conveyed was £144,000, and that which had nothing to do with distance was £282,000. Applying to these figures the estimated number of letters and newspapers, (126,000,000) passing through the office, there resulted a probable average cost of  $\frac{2\frac{1}{2}}{100}$  of a penny for each, of which  $\frac{1\frac{1}{2}}{100}$  was cost of transit and  $\frac{1\frac{1}{2}}{100}$  cost of receipt, delivery, &c. Taking into account, however, the much greater weight of newspapers and franked letters as compared with chargeable letters, the apparent average cost of transit became, by this estimate, but about  $\frac{2}{100}$ , or less than  $\frac{1}{10}$  of a penny.

A detailed estimate of the cost of conveying a letter from London to Edinburgh, founded upon the average weight of the Edinburgh mail, gave a still lower proportion, since it reduced the apparent cost of transit, on the average, to the thirty-sixth part of one penny. Hill in-

ferment and one or more organic acids. The use of the nectar is to attract insects, and thus to ensure cross-fertilization. The use of the excretions of the carnivorous plants is to dissolve the organic matter (usually insects) which has been deposited on the leaves, so as to bring it into a form in which it can be absorbed.

**Waste-products not excreted.** Many of the waste-products are not excreted, but remain in the plant. Thus the terpenes are indeed excreted by the cells which line the resin-ducts, but these ducts have no aperture on the surface of the plant. Similarly the caoutchouc and gutta-percha which are contained in the laticiferous tissue of certain plants have no means of egress. This is also true of the tannic acid, of the calcium carbonate (usually) and oxalate, of the alkaloids, and of silica. These substances are usually deposited in the cells. Calcium carbonate and oxalate are deposited in the form of crystals either in the cell-wall or in the cell-cavity, and silica in the cell-wall. In some cases calcium carbonate is deposited on cellulose processes which extend into the cell from its wall, the whole body being termed a "cystolith."

**3. Plastic Products.**—The principal non-nitrogenous plastic products are the carbohydrates and the fats (glycerides); to these, as suggested above, some of the organic acids are perhaps to be added.

**Starch.** Of the carbohydrates the substance which most demands attention is starch. Starch makes its appearance in the form of minute granules in chlorophyll-corpuscles in which constructive metabolism is being actively carried on. It was thought that it was the immediate product of the decomposition and recombination of carbon dioxide and of water in the corpuscle under the influence of light, the process being represented by some such equation as the following—

Increased knowledge of the conditions under which starch makes its appearance in plants has, however, made it evident that this is not the case. Starch may be regarded as the first *visible* product of the constructive metabolism going on in a chlorophyll-corpuscle, but it is not the first non-nitrogenous substance formed. That, as has been pointed out, is probably a body allied to formic aldehyde. The starch is formed as one of the products of the decomposition of the protoplasm of the corpuscle. That this is so is made evident when the formation of starch in parts of plants which are not green and which are not exposed to light is considered. In the cells of these parts there are certain small colourless protoplasmic bodies which are termed "starch-forming corpuscles" or "leukoplasts," and it is by these that the starch-granules are formed. It appears that the starch-granule is formed in the first instance by the decomposition of a portion of the protoplasm of the corpuscle, successive layers of starch being deposited upon the primitive granule by the decomposition of successive layers of protoplasm. It is in this way that the stratified structure of these starch-granules is produced. There is no reason for assuming that the process of starch-formation in chlorophyll-corpuscles is essentially different from that in leukoplasts; on the contrary, in view of the close relationship of these bodies, the one being convertible into the other, there is every reason for believing it to be the same. There is, however, this functional difference between the synthetic processes, i.e., the construction of protoplasm, begin with such simple substances as carbon dioxide, water, and mineral salts, whereas in the latter they begin (see below) with tolerably complex substances, such, for example, as glucose and asparagin. Starch, then, is the immediate product, not of constructive, but of destructive metabolism.

**Glucose.** Various kinds of sugar, notably glucose and cane-sugar,

are also commonly to be found in plants. Glucose may be regarded as having been derived by the action of an unorganized ferment from one or other of the other carbohydrates, except in certain plants, the Onion for example, in which it appears to be formed in the chlorophyll-corpuscles in the first instance. Nothing is known at present Cane-sugar as to the mode of origin of cane-sugar, which exists in such large quantities in certain plants, as the Beet and the Sugar-cane.

With regard to the fats, it is commonly assumed that Fats. they are formed directly from the carbohydrates, because in oily seeds, for example, as the starch which they contain when young diminishes in quantity it is replaced by fats. There is, however, sufficient evidence to prove that the fats are the products of the decomposition of protoplasm. The disappearance of the starch in ripening oily seeds is due to its being used up in the construction of protoplasm, as the protoplasm undergoes decomposition in connexion with the formation of fat.

The nitrogenous plastic products are proteids and Proteids amides. There can be little doubt that the proteids may be derived from protoplasm. If the molecule of living protoplasm be regarded as an extremely complex one, there is no difficulty in inferring that proteid may be one of the products of the decomposition of the protoplasm-molecule. The amides may also be products of the Amides decomposition of protoplasm, or they may be formed from proteids by the fermentative action of living protoplasm or by the action of some as yet undiscovered unorganized ferment, as pointed out above.

It has been stated that the plastic products are, so called because they are substances which can be used in the constructive metabolism of plants. But it must not be inferred that they are so used immediately. The very fact that it is possible to detect their presence in considerable quantity is a proof that this is not the case. They are largely stored up either for the use of the plant itself at some future time, or for the benefit of the progeny of the plant. In a perennial plant, for example, plastic products are stored in the persistent parts for the use of the plant when it recommences its active growth; they are also stored up in seeds and spores to be used by the young plant during the early stages of germination. Plastic products thus stored up are termed "reserve materials," and the organs in which they are deposited are termed "depositories for reserve materials." The non-nitrogenous reserve materials are Non-starch stored up in the form of carbohydrates or of fats. The nitro-starch which is formed in the green parts of the plant (which is, be it observed, a temporary reserve material) is converted into a soluble substance, probably glucose, and is conveyed in solution to the depository; and from it, directly or indirectly, the non-nitrogenous reserve materials are formed. The reserve carbohydrates are stored up either in the insoluble or the soluble form. In the former case they are deposited as starch-granules, or as cellulose (as in the endosperm of the Date) in thick cell-walls; in the latter they exist as various forms of sugar in solution in the cell-sap. The starch-granules are formed in these depositories by the leukoplasts. From the soluble non-nitrogenous substance, probably glucose, together with nitrogenous substances conveyed to the cells, the leukoplasts construct protoplasm; and it is as the result of the decomposition of this protoplasm in a certain way that starch is formed. This is true also of the reserve cellulose. From the plastic materials, both nitrogenous and non-nitrogenous, which are supplied to the cells protoplasm is constructed, and the external layers of protoplasm undergo decomposition in such a way that cellulose is formed and deposited in successive layers upon the internal surface of the cell-wall. The various kinds of

sugar (cane-sugar in the Beech root, glucose in the Onion, inulin in the Dahlia root, mannite in the unripe fruits of the Olive and in some Agarics, trehalose in many Agarics) are probably formed more or less directly from the glucose conveyed from other parts to the depository in each case. The fats occur as reserve materials characteristically in seeds and sometimes in fruits; they are not stored up in any considerable quantity in any other kind of depository. They too are formed by the decomposition of protoplasm which has been constructed from plastic materials, nitrogenous and non-nitrogenous, which have been conveyed to the cells.

Nitro-  
genous  
reserve  
mate-  
rials.

The nitrogenous reserve materials are stored either in solution or as solid granules. In the former case they are amides, such as asparagin and glutamin, leucin and tyrosin, and are held in solution in the cell-sap; they are present characteristically in roots and tubers, but they have also been found, though in small quantity, in seeds. In the latter case these materials are stored in the form of proteids, chiefly globulins and peptones, and the granules in which they are deposited are termed "aleurone grains." The aleurone grain may consist simply of an amorphous mass of proteid, or a portion of the proteid may have crystallized out so as to form a crystalloid; in most cases the grain contains a small mass of mineral matter which consists, according to Pfeffer, of double phosphate of lime and magnesia. Aleurone grains occur characteristically in seeds, and they are especially well developed in oily seeds.

Value of  
reserve  
materials  
for  
growth.

When once deposited, the reserve materials suffer no further change, or at most the proteids may slowly undergo some alteration (globulin being converted into albuminate), so long as the organ in which they are deposited remains in an inactive condition. But when the external conditions become favourable the quiescent organ resumes its active life—in a word, it germinates—and the reserve materials which it contains then undergo chemical changes of such a nature as to convert them into substances which can readily travel to the seat of growth and can be used as plastic material by the growing cells. In a germinating seed, for instance, as the embryo grows the reserve materials of the seed diminish in quantity; they are evidently conveyed to the seedling, and are used by it in the construction of new protoplasm. Beginning with the non-nitrogenous reserve materials, the starch in starchy seeds and the cellulose in such seeds as the Date are converted into sugar; this is proved by the detection of sugar as well in the seed as in the seedling, and by the detection in the seed of an unorganized ferment which possesses the property of converting starch into sugar. In oily seeds the fats are replaced by starch, formed through the intermediation of protoplasm, and the starch so formed is converted into sugar. With regard to the reserve proteids, they are converted into amides, for it has been ascertained that, as they diminish in quantity, the amides, and notably asparagin, increase.

The effect of the absorption of these plastic substances by the embryo is that the cell-sap of its cells becomes charged with them, for the supply is more rapid than the consumption in the formation of protoplasm. If the seedling is growing under favourable conditions these substances gradually diminish in quantity. Some light has been thrown upon the nature of these conditions by the researches of Pfeffer. He found that Lupin seedlings grown in the dark contained a very large quantity of asparagin so long as they continued to live, but that if they were exposed to light the asparagin gradually diminished. But he ascertained further that mere exposure to light is not the cause of this, since the asparagin did not diminish in seedlings exposed to light in an atmosphere which contained no carbon dioxide. The disappearance of the asparagin depended, therefore, upon conditions which were

essential to the formation of non-nitrogenous organic substance by the seedlings. Now the Lupin seed is one which is particularly rich in nitrogenous reserve materials, the quantity of non-nitrogenous reserve materials being relatively small. The accumulation of the asparagin in the seedlings grown in the dark is then to be ascribed to the absence of an adequate supply of non-nitrogenous substance with which it could combine to form proteid. When the seedlings were exposed to light this supply was forthcoming, and then the asparagin disappeared.

#### Supply of Energy.

It is evident that the various chemical processes which make up the metabolism of plants involve an expenditure of energy; hence of the maintenance of the life of the plant is dependent upon a supply of energy.

In the case of animals the food affords the principal supply of energy. It consists for the most part of complex organic substances which represent a considerable amount of potential energy, and when these substances are decomposed in the body the potential energy appears in the kinetic form. This holds good also with reference to plants which are destitute of chlorophyll, for their food necessarily includes, like that of animals, complex organic substances. But with plants which possess chlorophyll the case is entirely different. Their food consists of inorganic substances which do not represent any considerable amount of potential energy; from these simple substances green plants build up complex organic substances which do represent a considerable amount of potential energy; it is evident, therefore, that green plants must be largely supplied from without with kinetic energy in some form or other. It has been already mentioned that the metabolic processes of plants are materially affected by external conditions, especially by the presence or absence of light, and by variations in the temperature of the surrounding medium. A somewhat elevated temperature is essential to the active life of all plants, but light is essential only to the life of those which contain chlorophyll. This naturally suggests that the energy requisite for the maintenance of the life of plants is obtained by them in the form either of light or of heat.

*Light.*—In discussing the constructive metabolism of green plants light it was pointed out that such can only assimilate their food—that source of it, can only construct protoplasm from it—when exposed to light, plant-whereas plants which do not possess chlorophyll can assimilate energy. their food in the absence of light. It is true that a green seedling can live for a time in continuous darkness and increase in light, but it does so, not by assimilating its food, but at the expense of the organic reserve materials which may be present in it. The fact of the dependence of green plants upon exposure to light suggests that the energy necessary for the processes of their constructive metabolism is obtained in the form of light, and that their chlorophyll enables them to avail themselves of this form of kinetic energy. The function of chlorophyll has been made clear by the researches of Timiriaseff and of Engelmann. They have shown that the evolution of oxygen by a plant containing chlorophyll, which is the expression of the first stages of constructive metabolism, is most active when the plant is exposed to those rays of the solar spectrum which correspond to the absorption-bands of the chlorophyll-spectrum; the more conspicuous the absorption-band, the greater is the degree of activity, so that the evolution of oxygen is most considerable in the rays between the lines B and C of the solar spectrum, at the junction of the red and the orange, which correspond to the absorption-band I in the chlorophyll-spectrum. It is, then, in consequence of this absorption by the chlorophyll that the kinetic energy of the solar rays is made available for the work of constructive metabolism in the plant. The whole of the kinetic energy absorbed by the chlorophyll is not converted into potential energy; still the chlorophyll-corpusele appears to be a very perfect machine in this respect, for, according to Timiriaseff's calculations, it converts into the potential form as much as 40 per cent. of the absorbed energy. Inasmuch as light exercises so great an influence upon the constructive metabolism of green plants, it may be inferred that it must indirectly affect the absorption of food-materials by the roots. Rudolph Weber has, in fact, ascertained that the greatest absorption of the essential ash-constituents takes place when the plant is kept exposed to those rays of light which are most efficacious in promoting its constructive metabolism.

The effect of light upon the destructive metabolism of plants appears to be unimportant. This subject has been investigated by means of observations upon the respiration of plants; and such a method is calculated to afford the necessary information, inasmuch as the activity of respiration may be taken as a measure of the activity of destructive metabolism.

It has been generally stated that chlorophyll is not formed in the absence of light. There are, nevertheless, certain cases in which its formation in complete darkness has been observed, provided

that the temperature has been sufficiently high, namely, in the cotyledons of some Conifers and in the leaves of Ferns. The colouring matter etiolin is formed in the corpuscles in darkness, but the conversion of this into chlorophyll can only take place, as a rule, under the influence of light. The formation of chlorophyll will take place in light of very low intensity, but, as Wiesner's experiments show, there is a lower limit of intensity below which light is inactive. With regard to the relative efficacy of the different rays of the spectrum in promoting the formation of chlorophyll, it appears from Wiesner's researches that all the rays between Fraunhofer's lines B and H promote it in different degrees, and further, in confirmation of older observations, that seedlings turn green more rapidly in the yellow than in any other part of the spectrum. This last statement is true only for light of moderate intensity; when the light is very intense the formation of chlorophyll takes place more rapidly in blue than in yellow light. The reason of this is that in intense light chlorophyll undergoes decomposition, or at least chemical alteration of the nature of oxidation, which goes on most actively in yellow light.

**Heat as source of energy.**—Plants behave in relation to temperature like the cold-blooded animals. When they are maintained at a low temperature they cease to exhibit any signs of life. The meaning of this is that at a low temperature the activity of the metabolic processes is so reduced that they appear to be altogether arrested. But the importance of a moderately high temperature for the maintenance of the active life of the plant is not, as might be supposed, that it affords a continuous supply of energy to be converted into work; it is rather that it determines the initiation of chemical processes which are carried on by means of energy obtained from other sources. Hence the supply of energy in the form of heat is relatively small as compared, on the one hand, with the supply of potential energy afforded by their food to the plants which do not possess chlorophyll, and, on the other hand, with the supply obtained in the form of light by plants which do possess chlorophyll.

It is not possible within the limits of this article to enter fully into the relations existing between plant-life and temperature. The following statements will at least indicate their general nature. In the first place, the tolerance of extreme temperatures is different for different plants, as determined in the case of any particular organ, such as the seeds for instance. Secondly, for each of the processes which can be studied separately, such as germination, growth, respiration, the formation of chlorophyll, the action of unorganized ferments, the evolution of oxygen by green plants in light, &c., there are three cardinal points of temperature to be noted—the minimum or zero point, at which the performance of the process is just possible; the optimum point, at which it is carried on with the greatest activity; the maximum point, at which it is arrested. But these different phenomena do not all stand in precisely the same relation to temperature,—that is, the cardinal points for the exhibition of any two or more of these phenomena by one and the same plant do not necessarily coincide. Thirdly, the larger the proportion of water in an organ, the more liable it is to be injured by exposure to extreme temperatures.

#### Expenditure of Energy.

We have now to ascertain what becomes of energy supplied to the plant. The matter may be briefly stated thus: a portion of it is stored up in the plant in the form of potential energy; the remainder is lost to the plant, being either spent in the performance of mechanical work in connexion with growth or movement, or given off, most generally in the form of heat, occasionally in the form of light, and possibly in the form of electricity. The storing-up of energy in the potential form may be termed the "accumulation of energy," the loss as the "dissipation of energy."

**1. Accumulation of Energy.**—The accumulation of energy is the necessary accompaniment of constructive metabolism; the formation of more and more complex organic substances involves the conversion of kinetic into potential energy. By taking into consideration the amount of organic substance formed by a plant from its first development to its death, it is possible to arrive at some idea of the amount of kinetic energy which the plant has stored up in the potential form. For the heat which is given out by burning the organic substance is but the conversion into kinetic energy of the potential energy stored up in the substance; it is but the reappearance of the kinetic energy which was used in producing the substance. The heat, for instance, which is given out by burning wood or coal represents the kinetic energy, derived principally from the sun's rays, by which were effected the processes of constructive metabolism of which the wood or the coal was the product. The amount of energy thus stored up by plants in the potential form is very large, because they produce relatively large quantities of organic substance.

**2. Dissipation of Energy.**—The expenditure of energy in connexion with growth and movement, and with the evolution of heat, light, and electricity, is dependent upon destructive metabolism, for the conditions which are essential to destructive metabolism are also those which are essential to the exhibition of these

phenomena. Taking growth, for example—that is, continuous change of form accompanied usually by increase in bulk—it appears that in an aerobiotic plant it is dependent upon the following external conditions, namely, a supply of free oxygen and an adequate temperature, conditions which are precisely those upon which the destructive metabolic processes of such a plant also depend. This is true in such plants of the other above-mentioned phenomena also. Anaerobiotic plants can grow when the conditions are such that they can induce active fermentation,—that is, when their destructive metabolism is active. After what has been said in the section on the "Nervous System" above (p. 38 *sq.*) about animal movement it is hardly necessary to prove that the movements of plants, which are of essentially the same nature as those of animals, depend upon destructive metabolism and involve a dissipation of energy.

An evolution of energy in the form of heat is the inseparable result of destructive metabolism. With regard to plants, it may be stated generally that the evolution of heat is not sufficiently active to raise the temperature of the plant-body above that of the surrounding medium, it being remembered that plants are constantly losing heat, principally by radiation and in connexion with transpiration. In organs, however, in which destructive metabolism is very active it is easy to detect a rise of temperature, especially when a large number of them are collected together. A good instance of this is afforded by germinating seeds; for example, a rise of temperature is a familiar fact in the process of the malting of Barley. It can also be readily observed in the case of opening flowers in dense inflorescences; Warming observed, for example, that, at the time of the opening of the flowers, the inflorescence of an Aroid (*Philodendron bipinnatifidum*) attained a temperature of 18°·5 C. above that of the air.

The evolution of light by plants is a phenomenon which has been known from the times of Aristotle and of Pliny, and is commonly spoken of as "phosphorescence." All the well-authenticated instances of luminosity are confined to the Fungi, to various Agarics, and to Schizomycetes (*Bacteria*). The so-called "phosphorescence" of decaying wood is due to the presence of the mycelium of *Agaricus melleus* (*Rhizomorpha*), and that of putrefying meat and vegetables to micrococci. See PHOSPHORESCENCE. The evolution of light is essentially dependent upon the life of the organism, and further, it is dependent upon the destructive metabolism; for it ceases when the organism is killed (as by dipping it into hot water), or deprived of its supply of free oxygen, which is essential to the metabolic processes.

In view of the changes, both chemical and physical, which are going on with greater or less activity in the various parts of a living plant it has not been unnaturally inferred that the electrical equilibrium is being constantly disturbed, and that differences of electrical potential energy may exist in different parts. Many experimenters have investigated this subject, and such differences have been apparently observed. It is impossible to enter here into a detailed consideration of the results obtained; it may suffice to state that in the majority of cases the electrical currents detected do not indicate a dissipation of the energy of the plant, but are due to physical causes, and in some cases even to the effect upon the organism of the apparatus employed for the purpose of detecting them. It has been clearly made out in certain instances that the currents persist in organs which have been suddenly killed in such a way as not to destroy their gross organization.

There is, however, one instance in which an electrical current has been detected which seems to be connected with the destructive metabolism of the plant. Burdon-Sanderson and Munk have both observed that, when the two electrodes are placed upon a mobile leaf of *Dionaea muscipula* (Venus's Fly-trap) when at rest, a certain electrical current is indicated by the galvanometer. When the leaf is stimulated, whether the stimulation be or be not followed by a movement, the direction of the observed current is suddenly reversed. This change in the direction of the current—or "negative variation," as it is termed—is, according to Burdon-Sanderson, the "visible sign of an unknown molecular process," which he considers to be "an explosive molecular change," of the same nature as the negative variation which follows upon the stimulation of the muscles and nerves of animals.

In concluding this part of the subject it may be well, for the sake of clearness, to draw up an account of the income and expenditure of a plant.

In the case of a plant possessing chlorophyll the income of matter consists of the food (salts, water, carbon dioxide, free oxygen), and the income of energy of kinetic energy in the form of light and heat, the former being the more important of the two items. The great bulk of the food absorbed is converted into organic matter, and is for the most part retained by the plant in the form of organized structures, of reserve materials, and of waste-products which are not excreted; but a certain proportion of it is lost in the form of the carbon dioxide and water exhaled in respiration, of oxygen exhaled by green parts in sunlight, and of excreted organic or inorganic matter. Besides these items of loss there are yet others. All plants lose a certain amount of matter in connexion with repro-

duction, for all plants throw off in the course of their lives certain portions of their structure in the form of seeds, spores, antherozoids, etc. Again, plants which persist for more than one period of growth lose matter by the falling off of certain of their organs and of portions of their structure,—for example, by the falling of the leaves in autumn, and by the shedding of bark, fruits, etc. With reference to the expenditure of energy, a large proportion of the income of energy remains stored up in the potential form in the organic matter which the plant accumulates. A dissipation of energy as heat and in connection with growth is common to all plants: in some there is dissipation of energy in the form of motion, in some in the form of light, in some, probably, in the form of electricity. A loss of energy—potential energy—occurs also when the plant loses organic matter in any of the ways mentioned above. These various items may be tabulated under the two heads of "income" and "expenditure." The water lost in transpiration is not considered, for it simply traverses the plant; only that amount of water is considered which may be assumed to enter into the processes of constructive metabolism or to be produced in the processes of destructive metabolism.

#### Plant possessing Chlorophyll

Income		Expenditure	
Matter. Food—	Inorganic salts.	Matter.	Organic substances formed.
	Carbon dioxide.		Carbon dioxide, evolved in respiration.
	Water.		Water, evaporated.
	Free oxygen.		Free oxygen, evolved in light.
Energy.	Days of light absorbed by chlorophyll.	Energy.	Excreted substances, organic or inorganic.
	Light.		Reproduction (spores, seeds, etc.).
	Heat.		Other losses (leaves, fruits, bark, etc.).
	Electricity.		Constructive metabolism.
			Growth Movement (in some cases).
			Heat. Light. Electricity (in some cases).
			Potential energy (when organic matter is stored or thrown off).
			Balance in favour of Plant.
			Matter.—Organic substances (including dyes, reserve materials, and unexcreted waste-products).
			Energy.—Potential energy, represented by the accumulated organic substances.

#### Plant destitute of Chlorophyll

Income		Expenditure	
Matter. Food—	Inorganic salts.	Matter.	Organic substances formed.
	Carbon dioxide.		Carbon dioxide, evolved in respiration.
	Water.		Water, evaporated.
	Free oxygen (in most cases).		Free oxygen, evolved in light.

			Energy.—Potential energy, represented by the accumulated organic substances.

#### Movement of Plants.

Movement.

It has been pointed out above that movement, including in the conception the slow movement of growth, is an item in the expenditure of energy by the plant. The phenomena connected with movement are of such physiological importance that it will be well to consider them rather fully.

In dealing with this large subject attention will be directed for the present simply to the external phenomena, leaving the internal causes and mechanisms till subsequently, and those presented by growing organs will be taken first.

1. *Growth*.—In commencing the study of growth it is important to have a perfectly clear idea of what the word means. It means the continual change in form of the body of the plant, or of any organ of it, the change being frequently accompanied by increase in bulk, though this is not necessarily the case. For the purposes of this article it will be convenient to use "growth" as meaning, unless expressly stated otherwise, growth in length, that is, the elongation of the organ along the line joining its base and its apex. The conditions upon which growth is dependent are—(1) a supply of plastic material for the formation of new protoplasm; (2) favourable external conditions, especially an adequate temperature; (3) a supply of free oxygen in the case of aerobiotic plants, or, in the case of anaerobic plants, of fermentable substance; (4) a supply of water to maintain the turgidity of the cells. Any variation in these essential conditions will lead to a variation in the rate of growth. The capacity for growth is limited, as a rule, to a certain period of the life of an organ and of its constituent cells; when this period is past growth ceases, however favourable the external conditions may continue to be.

Rate of growth.

The rate of growth of an organ is not uniform. At first the organ grows slowly, then more and more rapidly, until a maximum rapidity is reached, and then the rate diminishes until growth ceases altogether. This cycle of spontaneous variation in the rate of growth is known as the "grand period of growth." It can be conveniently studied by marking on the growing point of an organ a series of transverse zones of known length, and observing their relative elongation in a given time. It will be found that the

youngest (nearest the apex) have elongated slightly, that the elongation is greater the farther each successive zone is from the apex, until a zone of maximum elongation is reached; the elongation of the zones lying behind this will be found to be less and less, until at last zones will be found which have not elongated at all. In addition to the variations in the rate of growth in length of an organ which make up its grand period it is found, if its growth be watched from hour to hour, or at even shorter intervals, that it presents irregular variations, which are likewise to be regarded as spontaneous. Variations in the rate of growth may be induced by variations in the external conditions, especially by variations of temperature and of illumination. It will be of interest to inquire briefly into these relations between growth and temperature and growth and light.

Inasmuch as the decompositions which determine the evolution of energy in the plant are dependent upon temperature, their activity being promoted by a rise of temperature within certain limits, it will be readily understood that growth, which is one expression of the evolution of energy, should likewise be affected by variations in temperature. It has been found, in fact, that the growth of any given plant will only take place within certain limits of temperature, a lowest or minimum temperature on the one hand and a highest or maximum temperature on the other; and further, that between these two points there is one, the optimum temperature, at which the rate of growth is most rapid. Growth is more rapid at each degree as the temperature rises from the minimum to the optimum point; it is less rapid at each degree as the temperature continues to rise from the optimum to the maximum point; and conversely, growth is more rapid at each degree as the temperature falls from the maximum to the optimum, and less rapid at each degree as the temperature further falls from the optimum to the minimum. This dependence of growth on temperature, and this relation between different degrees of temperature and different rates of growth, may be conveniently spoken of as the "tonic influence" of temperature. The mere variation in temperature as such does not appear, as a rule, to affect the rate of growth. Roots exposed to rapid and considerable variations of temperature for some time are found by Pedersen to have grown to about the same extent as similar roots which had been growing for the same time at the mean temperature. The only case in which it appears that variation in temperature produces a distinct effect is afforded by Pfeffer's observations upon the opening and closing of flowers. He found that a rise of temperature caused the flowers to open and a fall to close, the opening or closing being an expression of the accelerated growth in length of the organ as a whole. This effect of variation of temperature is distinguished as the "stimulating" effect.

In considering the relation of light to growth we have principally to consider its influence as being an essential normal condition and of growth, its "tonic" influence,—that is, it is a question whether or light not light exercises any influence which can be regarded as "stimulating" on the rate of growth. Speaking generally, it may be stated that plant-organs, with the exception of ordinary flattened horizontally expanded leaves and other organs of similar organization, grow at least as well in darkness as in light,—that exposure to light is not an essential condition of their growth. With leaves and leaf-like organs the case is different. When plants are kept for some time in darkness one of the most striking features is the smallness of the leaves of the shoots which have been developed during that time. This is not to be ascribed to an absence of plastic material, for it is exhibited when plastic material is abundantly present in the tissues; nor can it be attributed to the fact that in darkness the leaves are not able to carry on the formation of organic substance, for it is not all leaves which remain small in darkness, but only those which have the organization described above. The long tubular leaves of the Onion, for example, continue to grow in darkness, and so do the long flattened leaves of lilies. The arrest of the growth of flattened horizontally expanded leaves in darkness is due to some peculiar effect, which we must regard as of a "tonic" nature, exercised by light upon the growing cells. Intermittent exposure to light for brief periods suffices to enable the leaves to carry on their growth in darkness, and it is not necessary that the light should be intense. The intermittent exposure induces in the leaf a condition, though it cannot be precisely stated what, which permits of the continuance of growth,—a condition which is termed "phototonus." Assuming that the organ is actually growing, we find that in all cases light retards the rate of growth, and this the more markedly the greater its intensity. Wiesner has, in fact, shown that growth may be altogether arrested by exposure of the growing organ to intense light. The effect of light in retarding growth has been ascertained by comparative measurements of similar organs growing, some in darkness others in light, and is proved negatively by the greater length usually attained by shoots which have grown in darkness for a given time as compared with that attained in an equal time by shoots growing in light. It appears that variations in the intensity of light, as such, affect the rate of growth. Pfeffer has

found that exposure to light caused certain flowers to open, and to darkness to close. Probably this is accompanied, as in the parallel case of temperature, by an acceleration of the mean rate of growth.

The relation of the long axis of a growing organ to the line of action of gravity appears also to affect its rate of growth. Elfring has found that the sporangiferous hyphae of *Phycomyces*, which normally grow vertically upwards, grow somewhat less rapidly when they are maintained in the inverse position, that their growth in length is more rapid in opposition to the action of gravity than in the same direction, and this he thinks is true of all organs which normally grow vertically upwards. Gravity would appear, therefore, to exercise a tonic influence on growth. The substitution for gravity of a considerable centrifugal force produced no apparent effect on the rate of growth.

**Direction of growth.** The direction of growth of an organ is determined partly by inherent and partly by external causes. Beginning with the inherent causes, we find that, when the action of external directive influences upon growing organs is as far as possible eliminated, the axis of growth—that is, the line joining the apex and the base—is approximately a straight line. Thus Vöchting has shown that, when growing shoots are caused to grow in darkness and to rotate slowly about a horizontal axis by means of an instrument termed a "clinostat," their long axes become straight. This is the expression of

**Inherent causes.** an inherent tendency which he terms "rectipetality." But the line of growth is not at all times straight; for instance, the apex of an organ growing vertically upwards does not travel upwards in a straight line, but oscillates from side to side of the vertical. This oscillation is termed "nutations," and is due to the fact that growth in length is not uniformly rapid on all sides of the growing organ, but that during any given period of time one side grows more rapidly than the others. This unequal growth, which we may term "heterauxesis," is apparently spontaneous. The particular path which the apex of an organ describes in the course of its growth depends upon the properties of the organ, a point which may now be conveniently dealt with.

**Properties of growing organs.** Some information as to the properties of an organ may be obtained from observation of its anatomical structure. For instance, cylindrical organs, such as many shoots, are radially symmetrical in structure, and they are in most cases found to be also physiologically radial. Some organs, again, such as the leaves of some *Ficus*, are bilaterally symmetrical in structure, and they are found to be physiologically bilateral. Other organs, finally, such as flattened expanded leaves, prothallia of Ferns, thalloid shoots of Liverworts, though, like the bilateral organs, they present two opposed surfaces, are not bilaterally symmetrical in structure, inasmuch as the tissues in relation with the two surfaces are differently constituted. Such organs are dorsiventral both anatomically and physiologically. The properties of an organ are not, however, always to be inferred from structure. In some cases radial symmetry of structure is accompanied by dorsiventral properties. This is the case, as Sachs has shown, with the shoots of *Tropaeolum majus* under certain circumstances.

The question now naturally arises, How are the peculiar properties induced? In some cases they can only be accounted for by regarding them as inherent; this is true of radial organs, of bilateral organs, and to a certain extent of dorsiventral organs. The lateral branches of dicotyledonous trees have, in many cases, been found to possess inherent dorsiventral properties. In other cases, however, dorsiventrality is induced. It has been found by Frank—and his observation has been corroborated by De Vries—that the dorsiventrality of the lateral shoots of Conifers is induced by their relation to gravity. When maintained in a horizontal position during their growth the side which is uppermost becomes the dorsal surface, the other the ventral surface. Again, Sachs has shown that the young shoot of *Tropaeolum* is radial, but that if it be exposed to strong unilateral illumination it exhibits dorsiventral properties, the more strongly illuminated side becoming the dorsal surface, and further, that the plane of dorsiventrality may be altered by causing the light to fall on a fresh side of the shoot. A similar case of the induction of dorsiventrality is offered by the thalloid shoot of *Marchantia*. Tracing the development of the shoot from a gemma, we find the gemma to be bilaterally symmetrical in structure and in physiological properties. It falls to the earth with one surface undermost, which becomes the ventral surface, whilst the upper surface becomes the dorsal. That the dorsiventrality is in this case induced by light is proved by the fact that, if an experiment be so arranged that the light falls on the under surface of the gemma, this becomes the dorsal surface, whilst the upper surface becomes the ventral.

The further question now arises, How can the nature of the properties of an organ be determined, if, as has been shown, it cannot always be determined by an examination of the structure? The answer is, that it can be determined by observing the mode of growth of the organ, and especially its response to the action of external directive influences. Thus, the spontaneous heterauxesis of a radial organ is such that each side in turn is the one which is growing with the greatest rapidity, so that, seen from above, the

apex will appear to describe a somewhat circular orbit, and its path upwards will be spiral. This kind of nutation is termed "revolving nutation," or "circumnutation" (Darwin). Similarly, in bilateral organs each of the two sides grows alternately the more rapidly, so that, seen from above, the apex appears to oscillate from side to side of the vertical, and its path will be a zigzag line. Also in dorsiventral, as in bilateral, organs each of the two sides grows alternately the more rapidly, but the period of alternation is much longer, and may occur only once during the whole period of growth. For instance, the young leaves of Ferns are rolled up upon their internal (dorsal) surfaces; they present what is known as "circinate vernation." This is due to the fact that at first the lower (ventral) surface of the leaf grows more rapidly than the upper (dorsal); it is only towards the end of the period of growth that the upper surface grows the more rapidly, and then the leaf expands. Special terms have been applied to these phases of growth; when the upper surface of the organ is growing the more rapidly the growth is said to be "epinastic," when the lower "hyponastic."

The spontaneous variations in the direction of growth of an organ thus afford some indication of the nature of its organization, but directive this is more clearly shown by its response to the action of external influences. These will now be taken in order.

**Radiant Energy.**—It will be convenient to consider separately the phenomena exhibited by organs of different physiological properties.

Beginning, then, with radial shoot-organs, it is usually found that Helio- when light falls upon one side of such an organ the organ curves tropism so as to direct its apex towards the source of light,—in other words, in radial that it tends to place its long axis parallel to the direction of the organs. incident rays. The effect of the unilateral illumination is to cause heterauxesis of the organ such that the side upon which the light directly falls is the one which grows the most slowly, and therefore becomes concave. Inasmuch as all curvatures induced by light are included under the term "heliotropism," organs which exhibit the kind of curvature above described may be said to be "positively heliotropic." As examples of positively heliotropic radial organs may be mentioned radial stems, the multicellular stipes of some Fungi (*Coprinus*, *Claviceps*), the sporangiferous hyphae of unicellular Fungi (*Mucor*, *Pilobolus*), radial leaves, such as those of the Onion, and, as exceptional cases, some roots (Onion, *Ranunculus aquatilis*). In other cases the effect of unilateral illumination is the reverse of the above: the organ curves so as to direct its apex away from the source of light, though it still tends to place its long axis parallel to the direction of the incident rays. Organs curving in this manner are said to be "negatively heliotropic." This condition has been frequently observed in roots, and among shoots it is characteristic of the hypocotyl of the Mistletoe. Many cases of negative heliotropism in shoots have been mentioned, particularly the tendrils of *Vitis* and *Ampelopsis*, in which its existence was first detected by Knight; but the apparent negative heliotropism in these cases is probably the expression of something altogether different, as will be subsequently pointed out. There appear to be some well-authenticated cases of a reversal of heliotropic properties in the course of development of certain organs. Hofmeister states that the floral peduncles of *Linaria Cymbalaria* are positively heliotropic, but that when the fruit has replaced the flower the peduncle is negatively heliotropic; and Wiesner states that the peduncle of *Helianthemum vulgare* is negatively heliotropic after fertilization has taken place. The nature of the heliotropic properties appears thus to vary with the biological conditions of the organs.

When organs are exposed throughout the whole period of their growth to unilateral illumination they usually take up a certain position which is termed the "fixed-light position," such that they curve towards the direction of incidence of the brightest light. In some cases this is not so. This may be explained by an absence of heliotropic sensitiveness, but in some cases it is due to the fact that the organs follow the daily course of the sun. Wiesner mentions *Sonchus oleraceus* as a striking example of the latter condition. The activity of the curvature stands in a direct relation to the intensity of the incident light. The same botanist has found that for the organs of each plant there is an optimum intensity of light which produces the maximum of heliotropic effect, and that any increase or diminution of this intensity is followed by a diminished heliotropic effect.

With regard to the relative heliotropic effect of rays of different wave-length, it has long been known that the rays of high refrangibility are much more powerful than those of low refrangibility. Wiesner finds the distribution of heliotropic effect in the spectrum to be more exactly this: the greatest curvature is produced by the rays at the junction of the ultra-violet and violet; from this point the heliotropic effect diminishes until, in the yellow, it disappears; it begins to manifest itself again in the orange, and increases until it reaches a small secondary maximum in the ultra-red. Heliotropic effect is by no means confined to the luminous rays of the spectrum. Wiesner, and more recently Wortmann and Barthélemy, have shown that the dark heat-rays possess it. The curva-

tures produced by the dark rays are sometimes designated by the term "thermotropism."

The effect of unilateral illumination is not immediately exhibited, nor does it cease immediately upon the withdrawal of the organ from light. If an organ be exposed for only a short time to unilateral illumination, it may not exhibit any curvature during the period of exposure, but will curve subsequently in darkness. The exposure had sufficed to induce heliotropic curvature. This Wiesner terms "photo-mechanical induction," but it is simply due to the slow response of the organ to the directive influence of the incident rays,—to a long "latent period."

Turning now to the part played by the growing organ in heliotropic curvature, it is clear that the curvature will largely depend upon the heliotropic sensitiveness of the organ, and it must be borne in mind that organs vary widely in this respect. The curvature is in all cases confined to the growing region of the organ, or, to put it more generally, to the region which is capable of growing. In connexion with this point, the further one naturally arises as to the seat of heliotropic sensitiveness. It is usually assumed that those zones which are growing most rapidly are those which are most sensitive, but Darwin found that in some cases (cotyledons of *Phalaris* and *Avena*, hypocotyls of Cabbage and Beet) illumination of the tip of the organ appeared to induce heliotropic curvature. This cannot at present be regarded as fully established.

With regard to the heliotropic phenomena presented by simply bilateral organs, such as the leaves of Irises, it will suffice to say that they are positively heliotropic.

**Heliotropism in dorsiventral organs.** The heliotropic phenomena presented by dorsiventral organs are more complicated. It has been observed that dorsiventral branches (including the tendrils of *Vitis* and *Ampelopsis* mentioned above), when exposed to vertical light, tend to assume a horizontal position, whereas in darkness they usually grow erect. Dorsiventral leaves usually remain horizontal in darkness. A full discussion of these facts cannot be entered upon here; a few remarks must suffice. It is argued by some, especially by De Vries, that the horizontal position of dorsiventral organs when exposed to light is due to negative heliotropism; but there is no adequate proof that this is really the case. Sachs says on the subject, "So far as I can apprehend the facts, the negative heliotropism of the *Marchantia*-shoot, and that of many other shoots which behave in the same way, is the same phenomenon as the epinasty of foliage-leaves described by De Vries." Detmer has in fact found that exposure to light, quite independently of the direction of the incident rays, induces the rapid growth of the dorsal surface of dorsiventral leaves—in a word, induces photo-epinasty. Continued photo-epinasty would clearly cause the organ to curve downwards below the horizontal plane, and this is occasionally actually the case. But more frequently the organ remains in the horizontal plane when the light falls vertically upon it, or, to put the case more generally, the organ takes up such a fixed-light position that its long axis is at right angles to the direction of the incident rays. Moreover, it has been ascertained that it is always the dorsal surface of leaves which is directed towards the brightest incident light. It is clear that, in addition to the induction of photo-epinasty, light exercises a directive influence upon the growth of these organs. The attempt has been made to explain this by ascribing to the dorsiventral organs merely the heliotropic properties which belong to radial organs, but this explanation is quite insufficient. They can only be accounted for by attributing to dorsiventral organs, as Frank has done, a peculiar heliotropic sensitiveness, which he terms "transverse heliotropism" and Darwin "diheliotropism," which manifests itself in the assumption of such a position that the dorsal surface of the organ is placed at right angles to the direction of the incident rays.

**Gravity.**—The influence of gravity in determining the direction of growth of an organ manifests itself in phenomena which are designated by the term "geotropism." We will again consider separately the phenomena which are presented by organs of different physiological properties.

**Geotropism of radial organs.** Beginning with radial organs, we find that a great number of them normally grow either upwards or downwards; thus, primary shoots grow upwards and primary roots grow downwards. If any attempt is made to alter the direction of growth of these organs they at once curve so as to regain their normal direction. That the direction of growth is actually the result of the action of gravity was first demonstrated by Knight. He caused seeds to germinate on a wheel revolving with sufficient rapidity to set up a considerable centrifugal force, and he found that the roots and stems of the seedlings behaved with regard to the direction of the centrifugal force precisely as they do with regard to that of gravity: the roots grew radially outwards, and the stems radially inwards. He states his conclusion thus: "I conceive myself to have proved that the radicles of germinating seeds are made to descend, and their plumules to ascend, by some external cause, and not by any power inherent in vegetable life; and I see little reason to doubt that gravitation is the principal, if not the only, agent employed in this case by Nature."

In conformity with the terminology used with reference to heliotropism, organs which grow towards the centre of the earth are said to be "positively geotropic" and those growing in the opposite direction "negatively geotropic." As examples of positively geotropic radial organs may be mentioned, in addition to primary roots, the hyphae of Moulds which penetrate into the substratum, the root-like filaments of *Vaucheria*, *Caulerpa*, and other *Algae*, the rhizoids of *Muscinæ*, the rhizomes of some plants, such as *Yucca* and *Cordylinae*. As examples of negatively geotropic radial organs may be mentioned, in addition to primary shoots, the stipes of Mushrooms, the sporangiferous hyphae of Moulds, the stalks of the receptacles of Liverworts, the setae of *Muscinæ*, the peduncles of many flowers, the climbing roots of various epiphytes. Cases of the absence of geotropic irritability are afforded by the hypocotyl of the Mistletoe, and by the aerial roots of various epiphytes. A reverse of its geotropic properties may take place in the course of the development of an organ. Vöchting has found, for instance, that the peduncle of the Poppy is negatively geotropic whilst the flower is in the bud, but positively geotropic during flowering and fruiting.

In dealing with these phenomena we have first to consider the effect of gravity acting at different angles. Sachs concludes, and his conclusion is generally accepted, that the geotropic influence of gravity is greatest when the long axis of the organ is at right angles to the vertical, and that it is zero when the long axis of the organ coincides with the vertical, whether the apex point upwards or downwards, or whether the organ be positively or negatively geotropic,—that is, if the force of gravity acting at any point of an organ be decomposed into two forces, the one acting at right angles to the long axis of the organ and the other along it, it is only the former which produces a geotropic effect. Sachs bases this view upon the fact that geotropic curvature is more rapidly produced when an organ is horizontal than when it is in any other position. Elfving has made observations which suggest a different view, namely, that the geotropic action of gravity upon an organ is greatest when that organ is removed as far as possible from its normal relation to the vertical.

The degree of geotropic sensitiveness is different in different organs. This is shown by the different directions of growth taken by different organs when grown under conditions which prevent to a sufficient extent other directive influences from producing any effect. For instance, primary roots grow vertically downwards, but lateral roots grow more or less nearly horizontally. It has been ascertained, by means of centrifugal force, that lateral roots can be induced to behave like primary roots if only the force is sufficient: lateral roots grow radially outwards on the wheel when the centrifugal force is  $4g$  ( $g$ =force of gravity). It may be inferred that their geotropic sensitiveness is one-fourth of that of primary roots. The response of an organ to the directive influence of gravity, as in the case of heliotropism, is not immediate, but is preceded by a long latent period. An organ placed horizontally will not begin to curve for some time, and if then placed vertically the curvature will proceed for some time. Geotropic curvature, like heliotropic curvature, is a phenomenon of induced heterauxesis, the result being the assumption by the organ of such a position that gravity ceases to exert any directive influence upon it. Primary shoots and roots, for instance, find the vertical to be their position of rest, whereas lateral branches take up a more or less inclined position. It appears that, generally at least, the most rapidly growing zones of organs are those in which geotropic influence is most active. It has been hitherto generally accepted that the seat of most active curvature was also the seat of geotropic sensitiveness. Darwin recently brought forward the view, based upon the behaviour of roots with their tips cut off, that, in the root at least, the tip is the seat of geotropic sensitiveness. This suggestion has given rise to a number of researches, the results of which are so conflicting that it is impossible at present to come to any definite conclusion on the subject.

With regard to the geotropic properties of simply bilateral organs (leaves of Irises, &c.) it need only be said that they are negatively geotropic.

Coming, finally, to the geotropic phenomena presented by dorsiventral organs, we find that many organs which when growing are exposed to light have a more or less oblique direction of growth, dorsiventral organs are clearly negatively geotropic (examples are afforded organs, by the runners of *Polygonum aviculare*, *Atriplex latifolia*, and others, by radical leaves, and by thalloid shoots of *Marchantia*). But some dorsiventral organs do not grow erect in darkness. Frank mentions the runners of *Fragaria lucida*, lateral branches of Conifers, and many dicotyledonous shrubs and trees as examples. He finds, further, that when these organs are placed otherwise than horizontally they curve until they come to lie in that plane, and, if they are placed in an inverse position so that their normally inferior surface (ventral) is uppermost, they twist on their own axes until the normal relation of their surfaces with respect to the vertical is attained; many leaves also behave in this way. Frank

accounts for these phenomena by ascribing to such dorsiventral organs a peculiar geotropic sensitiveness, which he terms "transverse geotropism," and Darwin "diageotropism." De Vries has severely criticized this assumption. He regards the curvatures of shoots and branches into the horizontal plane as being, to some extent, the expression of the negative geotropism of the stems interfered with by the weight of the leaves, and, to some extent, also the expression of those forms of spontaneous heterauxesis termed epinasty and hyponasty which were alluded to above. Similarly he accounts for the torsions observed by Frank by ascribing them to the unequal twisting moment of the leaves on the two sides of the shoot when in the inverse position. In view of the existence of diageotropism, it may be regarded as probable that diageotropism exists also. But at present the case for the latter is not sufficiently made out. More experimental evidence must be forthcoming before the assumption of diageotropism can be regarded as fully justified.

#### Hydro-tropism.

**Moisture.**—It has long been known that roots when brought into the neighbourhood of a moist surface curve towards it. For instance, when seeds are sown in a box of damp sawdust, the bottom of the box being perforated with sufficiently large holes, the roots of the seedlings grow downwards into the sawdust, and ultimately project through the holes. They then no longer grow vertically downwards, but curve so as to apply themselves to the moist surface offered by the bottom of the box. To these phenomena Darwin has applied the term "hydrotropism." Organs which curve in this way are said to be "positively hydrotropic"; but there are also "negatively hydrotropic" organs. Wortmann has observed, for instance, that the sporangiferous hyphae of *Phycomyces* curve away from a moist surface. The phenomena are precisely similar to those of heliotropism and of geotropism. The curvature is in this case also the expression of induced heterauxesis. It takes place in this case also with the greatest activity in the region of most rapid growth. Darwin came to the conclusion that the hydrotropic sensitiveness of roots at least is localized in their tips, a conclusion which, though opposed by Detlefsen and Wiesner, is so far confirmed by Molisch's results that it may be accepted as well founded.

#### Galvano-tropism.

**Electricity.**—Elfvig found that when a root is placed vertically between two electrodes it curves towards the positive electrode,—that is, against the direction of the current. In one case (Cabbage) the curvature was towards the negative electrode. Müller (Hettingen), in repeating Elfvig's experiments, found that the curvature was in all cases such as to tend to place the long axis of the root in the plane of the current, the curvature being towards the negative pole. These phenomena are spoken of as "galvanotropism." Müller found that the curvature was induced when the current traversed only the tip of the root, thus affording apparently another instance of localization of sensitiveness in the tip.

#### Substratum.

**The Substratum.**—Dutrochet long ago observed that the hypocotyl of the Mistletoe, in whatever position the seed may have been placed, assumes such a direction of growth that its long axis is perpendicular to the surface on which the seed has germinated. Sachs has shown, by means of rotation on the clinostat, that this position is assumed both by shoots and roots. It is clear that the substratum exercises a directive influence upon the organs growing either outwards from its surface or inwards into its surface, but the nature of this influence has not yet been investigated. It is certainly not to be ascribed, as Van Tieghem suggested, to the mere mass of the substratum. The effect of a cube of turf or a pot of earth would vanish entirely in comparison with the attraction of the earth,—in other words, with the influence of gravity. The phenomena are designated generally by the term "somatotropism."

#### Contact.

**Contact.**—The effect of contact upon the direction of growth of an organ must be clearly distinguished from the effects of considerable pressure. The latter are of two kinds: in the one case the pressure arrests the growth of that side of the organ which is exposed to it; in the other it excites the organ to active growth, particularly in thickness. Examples of the former effect are so common that they need not be specified; examples of the latter are afforded by the thickening of tendrils and of climbing stems when they have firmly grasped some support. The phenomena now to be considered are such as are induced by slight pressure. Striking instances of this are afforded by tendrils. A very slight touch suffices, in the case of the very sensitive, such as those of *Passiflora gracilis* and of *Sicyos angulatus*, to induce very perceptible curvature, which can be detected, according to Darwin,

#### Twinning of tendrils.

In order to illustrate the subject adequately a brief account will be given here of the more important phenomena connected with the twinning of tendrils. Darwin has shown that tendrils are not sensitive during the whole of their existence; speaking generally, they are not sensitive when they are either very young or full grown, and are most sensitive when they are about three-fourths grown. Darwin has also found that their sensitiveness is localized. In most the lower or basal part is either not at all sensitive or is sensitive only to prolonged contact. Most tendrils have their tips

slightly but permanently hooked, and the sensitiveness is localized in the concavity of the hook. In some cases (*Cobaea scandens*, *Cissus discolor*) they are sensitive on all sides; in *Mutisia* the inferior and lateral surfaces are sensitive. As a rule, when in its most sensitive condition the tendril is actively circumnavigating, so that it travels over a large area, and there is considerable probability that it will come into contact with some body around which it can twine. When contact takes place the tendril begins to curve round the support. As it does so new points of the sensitive surface are stimulated, and the curvature increases and extends until the whole of the tendril lying between the original point of contact and the apex is wound in a spiral coil round the support. In some cases this is all that takes place. In the great majority of cases, however, the coiling of the apical portion of the tendril round a support is followed by the spiral coiling of more or less of that portion of the tendril which lies between the original point of contact and the insertion of the tendril upon the stem, provided that this is mechanically possible. The spiral coiling of the basal part of the tendril involves, namely, a considerable shortening, and, if both the stem and the support are immovably fixed, this shortening cannot take place. The turns of the coil are not all in the same direction; they are grouped into two or more spires, separated by short straighter portions, the turns of any two successive spires being in opposite directions. This is a mechanical necessity associated with the spiral coiling of a filament attached at both ends. The spiral coiling of the basal part of the tendril usually begins just below the point of attachment to the support. The coiling of tendrils, like all the curvatures hitherto considered, is a phenomenon of induced heterauxesis. Hence it is that the possibility of the twinning of a tendril round a support depends upon the thickness of the support and upon that of the tendril. Most tendrils, inasmuch as they are very thin, can twine round strings, but those which are relatively thick can only twine round a support of some thickness, for there is a mechanical limit to the excess of elongation of the convex over the concave side. The spiral coiling of the untouched portion of the tendril has an especial interest, as it offers a striking illustration of the transmission of a stimulus. It is true that the tendrils of many plants, if they fail to come into contact with a support, likewise coil spirally; but this is a much slower process, and only begins at the time when the tendrils are ceasing to grow and to be sensitive.

Tendrils are not, however, the only organs which are sensitive to contact. Other instances are afforded by the petioles of most leaf-climbers, by shoots, and apparently by roots.

In the case of sensitive shoots Dutrochet observed that the twinning stem of *Cuscuta* is sensitive like a tendril. Von Mohl suggested that all climbing stems are sensitive, but both Darwin and De Vries were unable to detect the sensitiveness. This view of Von Mohl has been recently revived by Kohl, who finds that the internodes of climbing stems are sensitive to a long-continued pressure which is insufficient to produce any simply mechanical effect. Darwin found the young internodes of *Lophospermum scandens*, which is not a stem-climber, as also the peduncles of *Maurandia semperflorens*, to be sensitive to touch, and Kerner states that this is also the case with the peduncles of many flowers (Poppy, Anemone, Ranunculus, Tulip).

With regard to roots, Darwin was led to suspect, by observing Darwin the behaviour of the radicles of seedlings in their attempts to pass winian over obstacles in the soil, that the tip of the radicle is sensitive to curvatory organ, to the growing zones behind it, in which the necessary curvature is then effected. He made experiments by attaching small objects to one side of the tip of the radicle in various plants, by touching one side of the tip with caustic, and by cutting a thin slice off one side, and found in most cases that the radicle curved away from the touched or injured side, that the curvature is precisely the opposite of that performed by tendrils when touched. The peculiar curving of radicles has been termed the "Darwinian curvature." Darwin's conclusions as to the sensitiveness of the radicle have given rise to considerable discussion. It is clear, in the first place, as he himself showed, that radicles are not perceptibly affected by brief contact or by friction; the contact must be prolonged. Those who dissent from Darwin's view, such as Wiesner, Burgerstein, and Detlefsen, urge that the curvatures induced in his experiments are pathological. It seems probable that this objection is valid. It may be admitted at once in the case of the experiments made by means of slicing the root-tip or touching it with caustic. With regard to the effect of small objects, such as pieces of card, it appears that the curvature of the radicle is due mainly, if not entirely, to the substances used in attaching them. In some cases, for instance, they were attached by a drop of shellac. It has been shown that the mere presence of the drop of shellac is sufficient to induce the Darwinian curvature, and microscopical examination has proved that the part touched by the shellac had died away. Moreover, it is known that a radicle can grow downwards against considerable resistance: it can penetrate into mercury; it can perforate tinfoil without deflexion; Darwin, in fact,

estimates the force of downward growth of the radicle at  $\frac{1}{4}$  lb, and its lateral pressure, in particular cases, at 8 and 3 lb respectively. The evidence leads to the conclusion that the Darwinian curvature of roots is not the expression of sensitiveness to contact, but that it is the result of injury of one side of the root.

**Combined Effects.**—Now that the influences which determine the direction of growth have been individually considered, it is possible to account for the characteristic positions taken up by organs in the course of their development. In dealing with this subject it is convenient, as Sachs suggests, to classify organs, according to their ultimate position, into two groups,—those which, under normal conditions, have their long axes vertical and those which have their long axes more or less inclined to the vertical; the former Sachs terms “orthotropic” organs, the latter “plagiotropic.”

Orthotropic organs.

The direction of growth of plant-organs under normal conditions is the expression of the resultant effect of various external directive influences. To illustrate this in the case of orthotropic organs, let us consider the primary shoot and the primary root of a seedling growing under conditions which may be taken as normal. In the case of a shoot growing upwards into the air when light falls vertically upon it, its vertical upward growth is chiefly due to the action of gravity,—that is, it is the expression of the particular degree and quality of the geotropic sensitiveness of the shoot. Since the light is equally intense on all sides of the shoot, it exerts no directive influence. Orthotropism is then mainly due to negative geotropism. That this is so can be readily proved in various ways. For instance, the hypocotyl of the Mistletoe, as mentioned above, is not geotropic at all; hence it cannot be included among either orthotropic or plagiotropic organs, for it may grow vertically or it may grow obliquely, its direction of growth being determined chiefly by its somatotropism. Again, when a normally orthotropic organ is grown in darkness on a clinostat its direction of growth is horizontal. Passing now to the case of primary roots growing in the earth, when the conditions are normal—that is, especially when the earth is uniformly moist around the root—their direction of growth is vertically downwards. This is chiefly due to their strong positive geotropism. Let us suppose, now, that the conditions of growth of these organs are somewhat different from those which we have regarded as normal; let us suppose that the shoot or the root is exposed to lateral light, or that the soil about the root is not equally moist on all sides. In the former case, the action of light will tend to induce heliotropic curvature, but it will depend upon the relative strength of heliotropic and of geotropic sensitiveness whether or not a curvature actually takes place. In the case of most orthotropic shoots a curvature (positive) would take place, thus showing the heliotropic sensitiveness of shoots to be greater than the geotropic, but in some instances it would not take place; in the case of most orthotropic roots no curvature would take place, but in some instances (*Sinapis alba* and others) a curvature (negative) would take place, showing that in most cases the heliotropic sensitiveness of roots is less than their geotropic sensitiveness. The unequal moisture in the soil around the root would cause hydrotropic curvature, inasmuch as the sensitiveness of roots to the influence of moist surfaces is greater than their sensitiveness to gravity.

Plagiotropic organs.

We will deal with plagiotropic organs in a similar way. The majority of such are lateral members, as branches, leaves, &c. The direction of growth of a lateral member, certainly of branches of stems and roots and probably also of leaves, is at first determined by its relation to the parent axis. It has been found—by Dutrochet, Sachs, and others—that at their first development the long axes of lateral organs make a definite angle—termed the “proper angle”—with the long axis of the parent organ. Dutrochet thought that the proper angle was in all cases a right angle, that the relation of lateral organ to parent axis was of the nature of somatotropism; but this is a too general statement. The original direction of growth of a lateral organ determined by its proper angle would be maintained, in the absence of internal directive influences, by its rectipetality, but in nature it is affected by light, by gravity, &c. Lateral shoot-branches, for example, are either inherently dorsiventral or they become dorsiventral under the influence of gravity or of unilateral illumination; they are then diheliotropic, though the manifestation of their diheliotropism may be interfered with by photo-epinasty; they are usually negatively geotropic. Their direction of growth—that is, the direction of their long axes when mature—is the resultant effect of diheliotropism and of negative geotropism. In the case of lateral root-branches these are plagiotropic but radial; they grow outwards, slightly inclined downwards below the horizontal; as they grow in the dark,—assuming that the moisture of the soil around them is uniform,—their direction of growth is affected to some extent by their slight positive geotropism. Though their geotropic sensitiveness is slight, their hydrotropic sensitiveness is great, so that their direction of growth is often very much modified by their coming into relation with moist areas of soil.

A complicated case of the action of a number of directive influences is afforded by climbing stems, and it may be worth while to specially consider it. When the stem is young and extends only

a few inches above the ground it appears to be growing almost vertically upwards, but as it elongates the last-formed internodes exhibit well-marked circumnutation. It continues to grow upwards mainly in virtue of its negative geotropism, the direction of its growth being little, if at all, affected by light in consequence of its low degree of heliotropic sensitiveness. If now one of the young growing apical internodes comes into contact with a vertical support it begins to twine around it in virtue of the sensitiveness to permanent though slight pressure which, as mentioned above, these organs possess, the direction of the curvature round the support being also that of circumnutation. The coils formed are nearly horizontal when the support is thick and become more nearly vertical as the support grows thinner; in any case, the steepness of the spire always increases after it is first formed, its diameter is thus diminished, and the stem gains a firm grip of the support. As the stem twines round the support it undergoes torsion around its own axis, so that any one side maintains throughout the same position, whether it be directed inwards, towards the support, or outwards or laterally. The direction of torsion may be either the same as that of coiling or the reverse,—that is, either homodromous or antidromous. The direction of torsion appears to depend principally on the relation between the thickness of the climbing stem and that of the support, and on the smoothness or roughness of the surface of the support; when the support is relatively thin the torsion is homodromous, but when it is relatively thick the torsion is antidromous; with smooth supports, up to a certain limit of thickness, the torsion is homodromous, and with rough supports, down to a certain limit of thinness, the torsion is antidromous; in a word, the direction of torsion is determined by the degree of friction between the climbing stem and the support.

**2. Movements.**—We pass now to the consideration of movements other than those associated with growth, and we take first movements exhibited by protoplasm. These may be classified into two categories,—(1) those which are performed by naked protoplasm, by protoplasm, that is, which is not enclosed in a cell-wall; (2) those exhibited by protoplasm enclosed in a cell-wall. The movements of naked protoplasm are effected in two ways,—either by the protrusion of portions of the protoplasm, termed “pseudopodia,” or by permanent flagelliform protoplasmic filaments, termed “cilia”; the first kind of movement is known as “ameboid,” the second as “ciliary” movement. The ameboid movement is exhibited, though rarely, by isolated cells—for instance, by the zoospores of the *Myxomycetes*—and characteristically by those large aggregates of cells which constitute the plasmodia of this group of Fungi. The pseudopodia are thrown out at first as protrusions of the denser hyaline outer layer of the mass of protoplasm, the ectoplasm, and into this the more watery granular internal protoplasmic substance, the endoplasm, gradually flows. The repeated formation of pseudopodia in any given direction will result in locomotion taking place in that direction. The ciliary movement is characteristic of zoospores and of antherozoids. In some cases the organism, as in the case of *Volvox* and *Pandorina*, passes a large part of its existence in the mobile condition, and then the protoplasm is enclosed within a cell-wall which is perforated by the cilia. The number of cilia may be only one; more commonly in zoospores it is two, and sometimes four; occasionally the cilia are numerous, as in the zoospores of *Vaucheria* and *Edogonium*; in antherozoids they are usually numerous. The cilia are constantly performing a lashing movement, which causes the organism to move forward and at the same time to rotate on its own axis.

In considering the movements of protoplasm when enclosed within a cell-wall, the typical structure of a plant-cell, as described at the beginning of this section (p. 44), must be borne in mind. In many cells the vacuole is found to be traversed by protoplasmic filaments which extend between one part of the primordial utricle and another. These filaments are continually varying in number, in position, and in size; they are formed and withdrawn in the same manner as the pseudopodia of naked masses of protoplasm. This kind of movement is, in fact, ameboid movement exhibited by protoplasm enclosed within a cell-wall. In all actively living protoplasm, whether naked or enclosed in a cell-wall, a streaming of the more fluid endoplasm can be observed, the direction and rapidity of the current being clearly shown by the granules which are carried along in it. This is very conspicuous in closed cells (as in leaf-cells of *Vallisneria spiralis* and root-hairs of *Hydrocharis morsus Ranae*) when the whole of the endoplasm rotates in a constant direction.

**Movements of Mobile Organs.**—With regard now to the movements exhibited by mobile organs, to the “movements of variation” as they are sometimes termed,—sometimes they are spontaneous, like variations the protoplasmic movements just considered; in other cases they are only performed in consequence of stimulation: they are induced. Instances of spontaneous movements of variation are, for reasons to be given hereafter, comparatively rare. A case in point is afforded by the Telegraph Plant, *Hedysarum (Desmodium) gyrans*. Under favourable conditions, particularly of temperature, the two lateral leaflets of the trifoliate leaf move upwards and downwards, their

apices describing nearly a circle, a revolution taking from two to five minutes. A familiar example of an induced movement is afforded by the leaves of the Sensitive Plant (*Mimosa pudica*). When a leaf is touched the lateral leaflets close in pairs, folding upwards and forwards, and, if the stimulus be strong enough, the main petiole sinks downwards. The movement of this plant is of special interest, inasmuch as it affords an instance of the transmission of a stimulus. It suffices, namely, to touch the terminal leaflet to cause the closing of the successive pairs of lateral leaflets and the sinking down of the main petiole. Another example of induced movement is afforded by the so-called "sleep" of plants; the leaves of many plants, namely, take up during the night a position different from that which they take up during the day. Taking the Sensitive Plant as an example, during the day its leaflets are widely expanded, and its main petioles are directed obliquely upwards; at night its leaflets are folded together and its main petioles are directed obliquely downwards; it takes up at night, in fact, a position similar to that which is induced by a touch. Excessive illumination tends to induce closing. Other examples are afforded by the mobile stamens of the *Cynareæ* and of *Berberis* and *Mahonia*.

The relation of these movements to external conditions is as follows:—

**External conditions of these movements.** 1. *Temperature*.—These movements, like the slow movement of growth, only take place within certain limits of temperature, which, however, vary in different cases. Movements of protoplasm, speaking generally, will only go on at temperatures between 0° and 50° C., and between these limits there is an optimum temperature at which they are most rapid. In the case of movements of variation the lower limit lies considerably higher, from 15° to 20° C. The foregoing illustrates the tonic relation between temperature and movement. Sudden changes of temperature have a stimulating effect. For instance, Dutrochet observed that the protoplasm of the internal cells of a *Chara* exhibited rotation in water at 7° C., which soon ceased when the plant was placed in water at 32° C.; after some time the movement returned, and was again arrested on replacing the plant in water at 7° C.

2. *Light*.—In most cases of protoplasmic movements light appears to exert no influence; in other cases it exerts a tonic influence. For instance, Engelmann has discovered a form of *Bacterium*, termed by him *Bacterium photometricum*, which is only mobile when exposed to light. Again, organs which exhibit spontaneous movements of variation, like the leaflets of *Hedysarum*, or induced movements, like the leaflets of *Mimosa*, lose their power of movement when kept in darkness for a day or two. Exposure to light, or, as it is termed, the state of "phototonus," is an essential condition of their movement. Bright light tends to arrest movement. For instance, the protrusion of pseudopodia by the plasmodium of *Phytium septium* is less active in light than in darkness. This is well shown in the sleep of plants, alluded to above. The "diurnal position" of the leaves is due to exposure to light, the "nocturnal position" to its absence. This is perhaps most clearly exhibited by the Sensitive Plant. Under the normal alternation of day and night the leaves assume alternately the diurnal and nocturnal positions. If a plant be kept for some time in darkness, at a suitable temperature, it will be found that the leaves exhibit periodic movements of opening and closing. They are, in fact, endowed, like those of the Telegraph Plant, with the power of spontaneous movement, which is arrested when the plant is exposed to light. Variations in the intensity of light act as stimuli. For instance, a sudden variation will cause the closing of the leaves of *Mimosa*. Light also exerts a directive influence on mobile protoplasm in some cases. For instance, when bright light falls obliquely on a plasmodium of *Ethidium septium*, it causes it to creep away from the light. Again, the chlorophyll-corpuscles in the cells of leaves exposed to bright light are found to accumulate on those surfaces of the cell which are least exposed, to assume what is termed the position of "apoptosis," a change of position which is due to movements in the protoplasm in which the corpuscles are embedded. Finally, the direction of movement of ciliated zoospores swimming in water is affected by light. When light falls obliquely upon a vessel of water containing zoospores, they place themselves so that their long axes are more or less nearly parallel to the direction of the incident rays, and it is along this line that they move. They may either move towards the incident light or away from it, the direction being apparently determined by the intensity of the light, by the age of the zoospores, and by the amount of oxygen in the water. Protoplasmic masses which respond to the directive action of light are said to be "phototactic."

3. *Other Stimuli*.—It has been mentioned that movements may be induced in the Sensitive Plant by mechanical stimulation, by variations of temperature, and variations in the intensity of light. They may also be induced by electrical and chemical stimuli. The effect of electrical stimuli on protoplasm exhibiting the amoeboid movement is to cause retraction of the pseudopodia. It arrests also the rotating movement of the protoplasm for a time.

4. *Oxygen*.—The presence of oxygen is an essential condition of movement of any kind, in the case at least of aerobic plants.

It appears that anaerobic plants (*Schizomycetes*) are mobile in the absence of oxygen.

*Nature and Mechanism of Movements*.—On comparing the statements which have been made above as to the movements of growing organs and of mature mobile organs, their general similarity is at once apparent. The spontaneous movement of growth is to move, comparable to the spontaneous movements of protoplasm and of mature mobile organs, and the performance of the former is dependent upon the same external conditions as the latter. The reaction to the influence of external agents is the same in many instances; for example, strong light arrests growth, and it arrests also the spontaneous movements of the leaves of *Mimosa* and other plants, and contact stimulates tendrils as it stimulates the leaves of the Sensitive Plant. Again, light exercises a directive influence on the growth of growing organs; it also exercises a directive influence on the movements of zoospores and plasmodia. These considerations lead to the conclusion that the causes of the movements must in all cases be the same.

It has been already pointed out that growth and movement are expressions of the expenditure of energy on the part of the organism, that they are dependent upon the decomposition of some complex substance forming part of, or at least present in, the protoplasm. The conditions which are essential to movement of any kind are, then, these: that the decomposable substance in question is formed and decomposed in sufficient quantity, in other words, that the protoplasm is irritable; that the protoplasm is capable of manifesting by a molecular change, which may be accompanied by a change in external form, the evolution of energy attending the decomposition; and, finally, in the case of protoplasm surrounded by a cell-wall, that the anatomical structure is such as to permit of a movement ensuing upon the change in the protoplasm. It is clear that, if the cell-wall is rigid, no change in the protoplasm can cause a change in form of the cell as a whole.

We may now consider movement as being due to the Spontaneous decomposition of the decomposable substance whereby the protoplasm undergoes a molecular change. The automatic movement of the protoplasm not unfrequently takes place, as in the case of the Telegraph Plant, at regular intervals, so that the movement is rhythmic or periodic. Spontaneous movement is most active when a certain favourable combination of external conditions is ensured; any variation in the combination leads to a diminution in the activity, or even to complete arrest, of the movement. External conditions may affect the process either of formation or of decomposition of the decomposable substance. For instance, movements are arrested at a low temperature, most probably because either the formation of the decomposable substance or the necessary explosive decomposition does not take place under such circumstances with sufficient activity. Again, when movement is arrested at a high temperature, or by continuous darkness, it is probably for similar reasons. In this way the tonic effect of external conditions may be accounted for. The stimulating effect of external agents may be accounted for in a similar manner.

Movement, whether spontaneous or induced, is regarded as a phenomenon of contractility (see above, p. 13), but we have at present no knowledge of the exact nature of the molecular changes which constitute a contraction. It must be borne in mind not only that protoplasm contracts, but that, after contraction, it returns to its condition of rest. Spontaneous movement is the expression of automatic contraction. External tonic conditions either promote or retard movement, by either promoting or retarding contraction and recovery. Stimuli induce contraction.

The mechanism of the movements of protoplasm-masses appears to be as follows. Taking first the case of the amoeboid movement, ism of the protrusion of pseudopodia is due to a molecular change, of the nature of a contraction of the protoplasm, which takes place in the ectoplasm at the spot where the pseudopodium is to be formed, an elevation being gradually produced into which the more fluid endoplasm is, as it were, sucked. The rotating movement of protoplasm appears to depend upon a kind of amoeboid movement taking place constantly in one direction,—to be, that is, a creeping movement. Ciliary movement appears to depend on the alternate contraction of each longitudinal half of the cilium. It is not possible at present to attempt any explanation of the directive influence of light on moving protoplasm, but the fact itself is of great physiological importance.

The mechanism of the movements of organs, whether unicellular or multicellular, in which the cell-wall has to be considered is more complicated. The cells possess the structure described above: they consist of a cell-wall lined by the protoplasmic primordial utricle enclosing the cell-sap. They are, moreover, in a state of turgidity,—that is, they are tensely filled with water. The state of turgidity in a cell depends upon three conditions,—(1) upon a tendency to absorb more water in consequence of the presence of osmotically active substances dissolved in the cell-sap; (2) upon the resistance offered by the primordial utricle to the escape of water from the cell; (3) upon the elasticity of the cell-wall. The elasticity of the primordial utricle is so small that it may be

*Literature.*—The following works on the physiology of plants may be consulted: Sachs, *Lehrbuch* (3d Eng. ed., Oxford, 1882) and *Vorlesungen über Pflanzenphysiologie* (Leipzig, 1882); Pfeffer, *Pflanzenphysiologie* (Leipzig, 1881); Van Tieghem, *Étude de Botanique* (Paris, 1881); Darwin, *Climbing Plants* (1875) and *The Power of Movement in Plants* (1880).

PIACENZA (Fr., *Plaisance*; Lat., *Placentia*), a city of Italy, a bishop's see, and the chief town of a province, lies on the Lombard plain, 217 feet above sea-level, not far from the right bank of the Po, just below the confluence of the Trebbia. By rail it is 43 miles south-east of Milan and 35½ north-west of Parma. Formerly a place of considerable strength, it is still surrounded by walls with bastions and fosse in a circuit of 4 miles. The cathedral was erected between 1122 and 1233, in the Lombardo-Gothic style, under the direction of Santo da Sambuceto, on the site of a church of the 9th century which had been destroyed by earthquake. The west front has three doors with curious pillared porches. The campanile is a massive square brick tower 223 feet high; the iron cage attached to one of its windows was put up in 1495 by Ludovico il Moro for the confinement of persons guilty of treason or sacrilege. The crypt is a large church supported by one hundred columns. Sant' Antonino, which was the cathedral church till 877, and occupies the spot where it was reputed that St Barnabas preached to the people, was built by St Victor, the first bishop of Piacenza, in 324, restored in 903, rebuilt in 1104, and altered in 1857. It was within its walls that the deputies of the Lombard League swore to the conditions of peace ratified in 1183 at Constance. The brick vestibule (Il Paradiso) on the north side is one of the older parts of the building. San Francesco, a spacious edifice begun by the Franciscans in 1278, occupies the site of Ubertino Landi's palazzo, and is famous as the place where Agostino Landi harangued the people after the murder of Pierluigi, and where in 1848 the deputies of Piacenza proclaimed the annexation of their city to the Sardinian kingdom. San Sisto, which dates from 1499, and takes the place of the church founded in 874 by Angilberga (consort of the emperor Louis II) for the Benedictines, lost its chief attraction when Raphael's Sistine Madonna (now in Dresden) was sold by the monks in 1754 to Frederick Augustus III. San Sepolcro and Sta Maria della Campagna are both after Bramante's designs; the latter is rich in works of Pordenone. Sant' Anna, dating from 1334, was the church of the barefooted Carmelites. Of the secular buildings in the city the most interesting is the Palazzo Comunale, begun in 1281. In the main front the lower story, constructed of red and white marble, presents a series of five open pointed arcades; the upper story, in brick, has six very rich round-arched windows, each of five lights; and above the cornice rise forked battlements. The square in front is known as the Piazza dei Cavalli, from the two bronze equestrian statues of Ranuccio (1620) and his father Alexander, prince of Parma, governor of the Netherlands (1625). Both were begun after Vignola's designs by Margaret of Austria in 1553; but it was never completed, and since 1800 it has been used as barracks. Other buildings or institutions of

note are the old and the new bishop's palace, the fine theatre designed by Lotario Tomba in 1803, the great hospital dating from 1471, the library presented to the commune in 1846 by the marquis Ferdinando Landi, and the Passerini library founded in 1685. About a mile to the east of the city is the Collegio Alberoni, instituted in 1751 for the education of priests and missionaries. At a distance of about 2 miles in the opposite direction the Trebbia is crossed by a bridge of twenty-three arches, erected in 1825 at a cost of £47,000; the Austrians blew up two of the arches in 1859. Piacenza is an important point in the Italian railway system—the Lombardy, Piedmont, and Ligurian lines meeting there with those of Central Italy. Silk, cotton, and woollen goods, pottery, and hats are among the local manufactures. The population of the commune (which in this case is almost exactly identical with the city) was 34,985 in 1871 and 34,987 in 1881.

Piacenza, originally, it is supposed, a Ligurian and afterwards a Gallic town, was made a Roman colony in 219 B.C. While its walls were yet unfinished it had to repulse an attack by the Gauls, whose hopes were excited by the news of Hannibal's approach, and in the latter part of 218 it afforded protection to the remains of the Roman army under Scipio which had been defeated by the Carthaginian general in the great battle on the Trebbia. In 207 it withstood a protracted siege by Hasdrubal, Hannibal's brother, and thus contributed largely to the ultimate success of the Romans. Seven years later the Gauls surprised and burned the city; and the colony was so diminished in strength that in 190 it had to be recruited with three thousand families. In 187 it was connected with Rimini and the south by the construction of the Æmilian Way. During the later republic and the empire Placentia is named in connexion with a defeat of the forces of Marius in the neighbourhood (82 B.C.), a mutiny of Julius Caesar's garrison (49 B.C.), another mutiny under Augustus (41 B.C.), the defence of the city by Spurius, Otho's general, against Cæcina, Vitellius's general (69 A.D.), and the defeat of Aurelian by the Marcomanni outside the walls (271 A.D.). In 546 Totila reduced Piacenza by famine. Between 997 and 1035 the city was governed by its bishops, who had received the title of count from Otho III. In the latter part of the 12th century it was one of the leading members of the Lombard League. For the most part it remained Guelph, though at times, as when it called in Galeazzo Visconti, it was glad to appeal to a powerful Ghibelline for aid against its domestic tyrants. In 1447 the city was captured and sacked by Francesco Sforza. Having placed itself directly under papal protection in 1512, it was in 1545 united with PARMA (q.v.) to form an hereditary duchy for Pierluigi Farnese, son of Paul III. In 1746 a battle between the Franco-Spanish forces and the Austrians was fought under the city walls. In 1848 Piacenza was re-occupied by the Austrians and had to wait for its emancipation till 1859. Lucius Calpurnius Piso (father-in-law of Julius Caesar), Pope Gregory X., and Alexander Farnese, duke of Parma, were natives of the city. Among the local historians are Boselli, Rossi, Bonara, and Gemmi.

PIANOFORTE. The group of keyed stringed instruments, among which the pianoforte is latest in order of time, has been invented and step by step developed with the modern art of music, which is based upon the simultaneous employment of different musical sounds. In the

10th century the "organum" arose, an elementary system of accompaniment to the voice, consisting of fourths and octaves below the melody and moving with it; and the organ, the earliest keyed instrument, was, in the first instance, the rude embodiment of this idea and convenient means for its expression. There was as yet no keyboard of balanced key levers; batons were drawn out like modern draw-stops, to admit the compressed air necessary to make the pipes sound. About the same time arose a large stringed instrument, the organistrum, the parent of the now vulgar hurdy-gurdy; as the organ needed a blower as well as an organist, so the player of the organistrum required a handle-turner, by whose aid the three strings of the instrument were made to sound simultaneously upon a wheel, and, according to the well-known sculptured relief of St George de Boscherville, one string was manipulated by means of a row of stoppers or tangents pressed inwards to produce the notes. The other strings were drones, analogous to the drones of the bagpipes, but originally the three strings followed the changing organum. In the 11th century, the epoch of Guido d'Arezzo, to whom the beginning of musical notation is attributed, the Pythagorean monochord, with its shifting bridge, was used in the singing schools to teach the intervals of the plain-song of the church. The practical necessity, not merely to demonstrate the proportionate relations of the intervals, but also to initiate pupils into the different gradations of the church tones, had soon after Guido's time brought into use quadruplex-fashioned monochords, which were constructed with scales, analogous to the modern practice with thermometers which are made to show both Réaumur and Centigrade, so that four lines indicated as many authentic and as many plagal tones. This arrangement found great acceptance, for Aribo, writing about fifty years after Guido, says that few monochords were to be found without it. Had the clavichord then been known, this make-shift contrivance would not have been used. Aribo strenuously endeavoured to improve it, and "by the grace of God" invented a monochord measure which, on account of the rapidity of the leaps he could make with it, he named a wild-goat (*caprea*). Jean de Muris (*Musica Speculativa*, 1323) teaches how true relations may be found by a single-string monochord, but recommends a four-stringed one, properly a tetrachord, to gain a knowledge of unfamiliar intervals. He describes the musical instruments known in his time, but does not mention the clavichord or monochord with keys, which could not have been then invented. Perhaps one of the earliest forms of such an instrument, in which stoppers or tangents had been adopted from the organistrum, is shown in fig. 1, from a wood carving of a vicar choral or organist, preserved in St Mary's Church, Shrewsbury. The latest date to which this interesting figure may be attributed is 1460, but the conventional representation shows that the instrument was then already of a past fashion, although perhaps still retained in use and familiar to the carver.

FIG. 1.—Earliest existing representation of a Keyed Stringed Instrument from St Mary's, Shrewsbury (Primitive Clavichord). Before 1460. Drawn by Miss Edith Lloyd.

often represented in old carvings, paintings, and stained windows. It derived its name *regal* from the rule (*regula*) or graduated scale of keys, and its use was to give the singers in religious processions the note or pitch. The only instrument of this kind known to exist in the United Kingdom is at Blair Athole, and it bears the very late date of 1630. The Brussels regal may be as modern. These are instances of how long a some-time admired musical instrument may remain in use after its first intention is forgotten. We attribute the adaptation of the narrow regal keyboard to what was still called the monochord, but was now a complex of monochords over one resonance board, to the latter half of the 14th century; it was accomplished by the substitution of tangents fixed in the further ends of the balanced keys for the movable bridges of the monochord or such stoppers as are shown in the Shrewsbury carving. Thus the monochordium or "payre of monochordis" became the clavichordium or "payre of clavichordis"—pair being applied, in the old sense of a "pair of steps," to a series of degrees. This use of the word to imply gradation was common in England to all keyed instruments; thus we read, in the Tudor period and later, of a pair of regals, organs, or virginals.

The earliest known record of the clavichord occurs in some rules of the minnesingers, dated 1404, preserved at Vienna. The monochord is named with it, showing a differentiation of these instruments, and of them from the clavicymbalum, the keyed cymbal, cembalo (Italian), or psaltery. From this we learn that a keyboard had been thus early adapted to that favourite mediæval stringed instrument, the "cembalo" of Boccaccio, the "sautrie" of Chaucer. There were two forms of the psaltery:—(1) the trapeze, one of the oldest representations of which is to be found in Orcagna's famous *Trionfo della Morte* in the Campo Santo at Pisa, and another by the same painter in the National Gallery, London; and (2) the contemporary "testa di porco," the pig's head, which was of triangular shape as the name suggests. The trapeze psaltery was strung horizontally, the "istromento di porco" either horizontally or vertically,—the notes, as in the common dulcimer, being in groups of three or four unisons. In these differences of form and stringing we see the cause of the ultimate differentiation of the spinet and harpsichord. The compass of the psalteries was nearly that of Guido's scale; but, according to Mersenne, the lowest interval was a fourth, G to C, which is worthy of notice as anticipating the later "short measure" of the spinet and organ.

The simplicity of the clavichord inclines us to place it, in order of time, before the clavicymbalum or clavicembalo; but we do not know how the sounds of the latter were at first excited. There is an indication as to its early form to be seen in the church of the Certosa near Pavia, which compares in probable date with the Shrewsbury example. We quote the reference to it from Dr Ambros's *History of Music*. He says a carving represents King David as holding an "istromento di porco" which has eight strings and as many keys lying parallel to them; he touches the keys with the right hand and damps the strings with the left. The attribution of archaism applies with equal force to this carving as to the Shrewsbury one, for when the monastery of Certosa was built chromatic keyboards, which imply a considerable advance, were already in use. There is an authentic representation of a chromatic keyboard, painted not later than 1426, in the St Cecilia panel (now at Berlin) of the famous Adoration of the Lamb by the Van Eycks. The instrument depicted is a positive organ, and it is interesting to notice in this realistic painting that the keys are evidently boxwood as in the Italian spinets of later date, and that the angel plays a common chord—A with the right hand, F and C with the left. But diatonic organs

with eight steps or keys in the octave, which included the B flat and the B natural, as in Guido's scale, were long preserved, for Praetorius speaks of them as still existing nearly two hundred years later. This diatonic keyboard, we learn from Sebastian Virdung (*Musica getutscht und ausgezogen*, Basel, 1511), was the keyboard of the early clavichord. We reproduce his diagram as the only authority we have for the disposition of the one short key.

FIG. 2.—Diatonic Clavichord Keyboard (Guido's Scale) from Virdung. Before 1511.

The extent of this scale is exactly Guido's. Virdung's diagram of the chromatic is the same as our own familiar keyboard, and comprises three octaves and a note, from F below the bass staff to G above the treble. But Virdung tells us that even then clavichords were made longer than four octaves by repetition of the same order of keys. The introduction of the chromatic order he attributes to the study of Boetius, and the consequent endeavour to restore the three musical *genera* of the Greeks—the diatonic, chromatic, and enharmonic. But the last-named had not been attained. Virdung gives woodcuts of the clavichordium, the virginal, the clavichordium, and the clavichordium. We reproduce three of them (figs. 3, 6, and 12), omitting the virginal as obviously incorrect. All these drawings have been continually repeated by writers on musical instruments up to the present day, but without discerning that in the printing they are reversed, which puts the keyboards entirely wrong, and that in Luscinius's Latin translation of Virdung (*Musurgia, sive Praxis Musica*, Strasburg, 1536), which has been hitherto chiefly followed, two of the engravings, the clavichordium and the clavichordium, are transposed, another cause of error. Martin Agricola (*Musica Instrumentalis*, Wittenberg, 1529) has copied Virdung's illustrations with some differences of perspective, and the addition, here and there, of errors of his own.

FIG. 3.—Virdung's Clavichordium, 1511; reversed facsimile.

Still vulgarly known as monochord, Virdung's clavichord was really a box of monochords, all the strings being of the same length. He derives the clavichord from Guido's monochord as he does the virginal from the lute; but, at the same time, confesses he does not know when, or by whom, either instrument was invented. We observe in this drawing the short sound-board, which always remained a clavichord peculiarity, and the straight sound-board bridge—necessarily so when all the strings were of one length. To gain an angle of striking place for the tangents against the strings the keys were made crooked, an expedient further rendered necessary by the "fretting,"—three tangents, according to Virdung, being directed to stop as many notes from each single group of three strings as in modern times; each tangent thus made a different vibrating length of string. In the drawing the strings are

merely indicated. The German for fret is *Bund*, and such a clavichord, in that language, is known as a "gebunden" one, both fret (to rub) and *Bund* (from *binden*, to bind) having been taken over from the lute or viol. The French and Italians employ "touche" and "tasto," touch. Praetorius, who wrote a hundred years later than Virdung, says two, three, and four tangents were thus employed in stopping. The oldest clavichords extant have no more than two tangents to a note formed by a pair of strings, no longer three. Thus seven pairs of strings suffice for an octave of twelve keys, the open notes being F, G, A, B flat, C, D, E flat, and by an unexplained peculiarity, perhaps derived from some special estimation of the notes which was connected with the church modes, A and D are left throughout free from a second tangent. A corresponding value of these notes is shown by their independence of chromatic alteration in tuning the double Irish harp, as explained by Galilei in his treatise on music, published in 1581. Adlung, who died in 1762, speaks of another fretting, but we think it must have been an adaptation to the modern major scale, the "free" notes being E and B. Clavichords were made with double fretting up to about the year 1700,—that is to say, to the epoch of J. S. Bach, who, taking advantage of its abolition and the consequent use of independent pairs of strings for each note, was enabled to tune in all keys equally, which had been impossible so long as the fretting was maintained. The modern scales having become established, Bach was now able to produce, in 1722, *Das wohltemperirte Clavier*, the first collection of preludes and fugues in all the twenty-four major and minor scales for a clavichord which was tuned, as to concordance and dissonance, fairly equal.

The oldest clavichord, here called manicordo (as French, *manicorde*, from *monochord*), known to exist is that shown in fig. 4. It will be observed that the lowest octave is

FIG. 4.—Manicordo (Clavichord) d'Eleonora di Montalvo, 1659; Kraus Museum, Florence.

here already "bundfrei" or fret-free. The strings are no longer of equal length, and there are three bridges, divisions of the one bridge, in different positions on the sound-board. Mersenne's "manicorde" (*Harmonie Universelle*, 1636), shown in an engraving in that work, has the strings still nearly of equal length, but divides the sound-board bridge into five. The fretted clavichords made in Germany in the last years of the 17th century have the curved sound-board bridge, like a spinet. In the clavichord the tangents always form the second bridge, indispensable for the vibration, as well as act as the sound excitors (fig. 5). The common damper to all the strings is a list of cloth, interwoven behind the tangents. As the tangents quitted the strings the cloth immediately

FIG. 5.—Clavichord Tangent.

stopped vibration. Too much cloth would diminish the tone of this already feeble instrument, which gained the name of "dumb spinet" from its use. The cloth is accurately painted in the clavichord Rotens's St. Cecilia (Dresden Gallery) plays upon,—interesting as perhaps representing that painter's own instrument. The number of keys there shown is three octaves and a third, F to A,—the same extent as in Handel's clavichord now in the museum at Melfstone (an Italian instrument dated 1726, and not fixed), but with a combined chromatic and short octave peculiarity in the lowest notes we shall have to refer to when we arrive at the spinet; we pass it by as the only instance in the clavichord we have met with. The clavichord must have gone out of favour in Great Britain and the Netherlands early in the 16th century, before its expressive power, which is of the most tender and intimate quality, could have been, from the nature of the music played, observed,—the more brilliant and elegant spinet being preferred to it. Like the other keyboard instruments it had no German name, and can hardly have been of German origin. Holbein, in his drawing of the family of Sir Thomas More, 1528, now at Basel, indicates the place for "Klavichord und ander Seytenspiel." But it remained longest in use in Germany—until even the beginning of the present century. It was the favourite "Klavier" of the Bachs. Besides that of Handel already noticed, there are in existence clavichords the former possession of which is attributed to Mozart and Beethoven. The clavichord was obedient to a peculiarity of touch possible on no other keyboard instrument. This is described by C. P. Emmanuel Bach in his famous essay on playing and accompaniment, entitled *Fewisch über die wahre Art das Clavier zu spielen* (An Essay on the True Way to play Keyboard Instruments). It is the "Bebung" (trembling), a vibration in a melody note of the same nature as that frequently employed by violin players to heighten the expressive effect; it was gained by a repeated movement of the fleshy end of the finger while the key was still held down. The "Bebung" was indicated in the notation by dots over the note to be affected by it, perhaps showing how many times the note should be repeated. According to the practice of the Bachs as handed down to us in the above mentioned essay, great smoothness of touch was required to play the clavichord in tune. As with the monocord, the means taken to produce the sound disturbed the accuracy of the string measurement by increasing tension, so that a key touched too firmly in the clavichord, by unduly raising the string, sharpened the pitch, an error in playing deprecated by C. P. Emmanuel Bach. This answers the assertion which has been made that J. S. Bach could not have been nice about tuning when he played from preference on an instrument of uncertain intonation.

The next instrument described by Viridung is the virginal (*virginalis* proper for a girl), a parallelogram in shape, with a projecting keyboard and compass of keys the same as the clavichordium. Here we can trace derivation from the psaltery in the sound-board covering the entire inner surface of the instrument: and in the triangular disposition of the strings. The latter in Viridung's drawing has an impossible position with reference to the keyboard, which renders its reproduction as an illustration useless. But in the next drawing, the clavicimbalum, this is rectified, and the drawing, reversed on account of the key-board, can be accepted as roughly representing the instrument so called (fig. 6).

There would be no difference between it and the virginal were it not for a peculiarity of keyboard compass, which emphatically refers itself to the Italian "spinetta," a name unnoticed by Viridung or by his countryman,

Arnold Schlick, who in the same year 1511, published his *Spiegel der Organbauer* ("Organ-builders' Mirror"), and

FIG. 5.—Viridung's Clavicimbalum (spinet) III; reversed position.

named the clavichordium and clavicimbalum as familiar instruments. In the first place, the keyboard, beginning apparently with B natural, instead of F, makes the clavicimbalum smaller than the virginal, the strings in this arrangement being shorter: in the next place it is almost certain that the Italian spinet compass, beginning apparently upon a semitone, is identical with a "short measure" or "short octave" organ compass, a very old keyboard arrangement, by which the lowest note, representing B, really sounded G, and C sharp in like manner A. The origin of this may be deduced from the psaltery and many representations of the regal, and its object appears to have been to obtain dominant basses for cadences,—harmonious closes having early been sought for as giving pleasure to the ear. We have found a hitherto unnoticed authority for this practice in Mersenne, who, in 1636, expressly describes it as occurring in his own spinet (*org. inute*). He says the keyboards of the spinet and organ are the same. Now, in his Latin edition of the same work he renders *espiniere* by clavicimbalum. We read (*Harmonie Universelle*, Paris, 1636, liv. 3, p. 107)—"Its longest string [his spinet's] is little more than a foot in length between the two bridges. It has only thirty-one steps ["*musules*"] in its keyboard, and as many strings over its sound-board [he now refers to the illustration], so that there are five keys hidden on account of the perspective,—that is to say, three naturals and two sharps ["*seines*," same as the Latin *scilicet*], of which the first is cut into two [a divided sharp forming two keys]; but these sharps serve to go down to the third and fourth below the first step, C & [tenor clef C], in order to go as far as the third octave, for the eighteen principal steps make but an eighteenth, that is to say, a fourth more than two octaves." The note we call F he, on his engraving, letters as C, indicating the pitch of a spinet of the second size, which the one described is not. The third and fourth, reached by his cut sharp, are consequently the lower A and G: or, to complete, as he says, the third octave, the lowest note might be F, but for that he would want the diatonic semitone B, which his spinet, according to his description, did not possess.<sup>1</sup> Mersenne's statement sufficiently proves, first, the use in spinets as well as in organs of what we now call "short measure," and, secondly, the intention of cut sharps at the lower end of the keyboard to gain lower notes. He speaks of one string only to each note: unlike the double and triple strung clavichord, these instruments, clavicimbalum, spinet, or virginal, derived from the psaltery, could only present one string to the mechanical plectrum which twanged it. As regards the kind of plectra earliest used we have no evidence. The little crow-quill points, Scaliger, who was born in 1484, ex-

<sup>1</sup> Mr A. J. Ellis (*History of Musical Pitch*, p. 318) sees the B in Mersenne's outline diagram.

board, which Mersenne's short measure, and the realization at that time of the independence of each key in the chromatic scale, may be taken when combined to explain.

FIG. 10.—Roman Clavicembalo, by Geronimo of Bologna, 1521; South Kensington Museum.

Hitherto such cut sharps have been assumed to be quarter tones, but enharmonic intervals in the extreme bass can have no justification. From the tuning of Handel's Italian clavicord already mentioned, which has this peculiarity, and from Praetorius we find the farther halves of the two cut sharps were the chromatic semitones, and the nearer halves the major thirds below what they appeared to be. Thomas Hitchcock (for whom there are dates 1664 and 1703 written on keys and jacks of spinets bearing Edward Blunt's name and having divided bass sharps) made a great advance in constructing spinets, giving them the wide compass of five octaves, from G to G, with very fine keyboards in which the sharps were inlaid with a slip of the ivory or ebony, as the case might be, of the natural. Their instruments, always numbered, and not dated as has been sometimes supposed, became models for the contemporary and subsequent English makers.

We have now to ask what was the difference between Scaliger's harpichordum and his clavicymbal. Galilei, the father of the astronomer of that name (*Dialogo della Musica Antica e Moderna*, Florence, 1581), says that the harpichord was so named from having resembled an "arpa giacente," a prostrate or "couched" harp,—proving that the clavicymbal was at first the trapezoidal-shaped spinet; and we should therefore differentiate harpichord and clavicymbal as, in form, suggested by or derived from the harp and psaltery, or from a "testa di porco" and an ordinary trapezoid psaltery. We are inclined to prefer the latter. The Latin name "clavicymbalum," having early been replaced by spinet and virginal, was in Italy and France bestowed upon the long harpichord, and was continued as clavicembalo (graveceimbalo, or familiarly cembalo only) and clavecin. Much later, after the restoration of the Stuarts, the first name was accepted and naturalized in England as harpsichord, which we will define as the long quill instrument shaped like a modern grand piano, and resembling a wing, from which it has gained the German appellation "Flügel." We can point out no long

instrument of this kind so old as the Roman cembalo at South Kensington (fig. 11). It was made by Geronimo of Bologna in 1521, two years before the Paris Portulapis spinet. The outer case is of finely tooled leather. It has a spinet compass of keyboard of nearly four octaves, E to D. The natural keys are of boxwood, gracefully arcaded in front. The keyboards of the Italian cembalo were afterwards carried out to the normal four octaves. There is an existing example dated 1626, with the bass keys carried out without sharps in long measure. It is surprising to see with what steady persistence the Italians adhered in making the instrument to their original model. As late as the epoch of Cristofori, and in his 1722 cembalo at Florence, we still find the independent outer case, the single keyboard, the two unisons, without power to reduce to one by using stops. The Italians have been as conservative with their forms of spinet, and are to this day with their organs. The startling "piano e forte" of 1598, brought to light from the records of the house of D'Este, by Count Valdrighi of Modena, after much consideration and a desire to find in it an anticipation of Cristofori's subsequent invention of the pianoforte, we are disposed to regard as an ordinary cembalo with power to shift, by a stop, from two unisons (forte) to one string (piano), at that time a Flemish practice, and most likely brought to Italy by one of the Flemish musicians who founded the Italian school of composition. About the year 1600, when accompaniment was invented for monody, large cembali were made for the orchestras to bring out the bass part—the performer standing to play. Such an instrument was called "archicembalo," a name also applied to a large cembalo, made by Vito Trasuntino, a Venetian, in 1606, intended by thirty-one keys in each of its four octaves—one hundred and twenty-five in all—to restore

FIG. 11.—Roman Clavicembalo, by Geronimo of Bologna, 1521; South Kensington Museum.

the three genera of the ancient Greeks. How many attempts have been made before and since Trasuntino to purify intonation in keyboard instruments by multiplying keys in the octave? Simultaneously with Father Smith's well-known experiment in the Temple organ, London, there were divided keys in an Italian harpsichord to gain a separate G sharp and A flat, and a separate D sharp and E flat.

Double keyboards and stops in the long cembalo or harpsichord came into use in the Netherlands early in the 16th century. We find them imported into England. The following citations, quoted by Rimbault in his *History of the Pianoforte*, but imperfectly understood by him, are from the privy purse expenses of King Henry VIII, as extracted by Sir Harris Nicolas in 1827.

"1530 (April). Item the vii daye paid to William Lewes for ii payer of virginalls in one coffer with iiii stoppes brought to Grenewiche iii li. And for ii payer of virginalls in one coffer brought to the More other iii li."

Now the second instrument may be explained, virginalls meaning any quilled instrument, as a double spinet, like that at Nuremberg by Martin Van der Beest, the octave division being movable; but the first cannot be so explained; the four stops can only belong to a harpsichord, and the two pair instrument to a double-keyed one, one keyboard being over, and not by the side of the other. Again from the inventory, after the king's death—

"Two fair pair of new long Virginalls made harp-fashion of Cipres, with keys of ivory, having the King's Arms crowned and supported by his Grace's beastes within a garter gilt, standing over the keys."

Rimbault saw in this an upright instrument, and such a one was not then impossible, Virdung's clavichord (fig. 12)

being no more than a horizontal harpsichord turned up upon its broad end, which a slight modification of the action rendered facile, but if upright, the two fair pair of new long virginalls would not have been "long"—but high. We explain "harp-fashion" according to Galilei's "arpa giacente," and are disposed to believe that we have here another double keyboard harpsichord. We read in an inventory of the furniture of Warwick Castle, 1584, "a faire paire of double

FIG. 12.—Virdung's Clavichord (upright Harpsichord), 1511.

virginalls," and in the Hengrave inventory, 1603, "one great payre of double virginalls." Hans Ruckers, the great clavichord maker of Antwerp, lived then too late to have invented the double keyboard and stops, evident adaptations from the organ, but we may not withhold from him the credit of introducing the octave string, so long attributed to him, which incorporated the octave spinet with the large instrument, to be henceforth playable without the co-operation of another performer. It had been attached to the bent or angle side of harpsichords, as shown in a modern instrument which forms part of the famous Plantin Museum at Antwerp, and also in one by Hans Ruckers himself, dated 1594, preserved in the Kunst und Gewerbe Museum, Berlin. The double harpsichord by that maker at the Conservatoire, Paris, dated 1590, which is four years earlier than the above, has the octave string. From that date until the last harpsichord was made by Joseph Kirkman in 1798, scarcely an instrument of the kind was made, except in Italy, without the octaves. Hans Ruckers had two sons, Hans the younger and Andries the elder, who followed and rivalled him in skill and reputation. Another Andries, the son of the former, appears to have done but little, at least for himself; but a nephew, Jan Couchet, a grandson of old Hans Ruckers, continued the prestige of this distinguished family, Huygens being a witness to the rare ability of Couchet. All these men, and, in fact, all the clavichord makers of Antwerp, belonged to the artist's guild of St Luke, the affiliation being recognized from the close alliance at that time of the arts, the painter having often as much to do with the musical instrument as the maker himself. The Ruckers harpsichords in the 18th century were fetching such prices as Bologna lutes did in the 17th or Cremona

violins do now. There are still many specimens existing in Belgium, France, and England. Handel had a Ruckers harpsichord, which may be the one long sought for and lately discovered by Mr Julian Marshall in Windsor Castle; it completes the number of sixty-three existing Ruckers instruments catalogued in Grove's *Dictionary of Music and Musicians*.

After the Antwerp make declined, London became pre-eminent for harpsichords,—the representative makers being Jacob Kirckmann and Burekhard Tschudi, pupils of a Flemish master, one Tabel, who had settled in London, and whose business Kirckmann continued through marriage with Tabel's widow. Tschudi was of a noble Swiss family belonging to the canton of Glarus. According to the custom with foreign names obtaining at that time, by which Haendel became Handel, and Schmidt Smith, Kirckmann dropped his final *n* and Tschudi became Shudi, but he resumed the full spelling in the facies of the splendid harpsichords he made in 1766 for Frederick the Great, which are still preserved in the New Palace, Potsdam. By these great makers the harpsichord became a larger, heavier-strung, and more powerful instrument, and fancy stops were added to vary the tone effects. To the three shifting registers of jacks of the octave and first and second unisons were added the "lute," the charm of which was due to the favouring of high harmonics by plucking the strings close to the bridge, and the "harp," a surdine or muting effect produced by impeding the vibration of the strings by contact of small pieces of buff leather. Two pedals were also used, the left-hand one a combination of a unison and lute, rendered practicable by first moving the "machine," a sixth stop, with the left hand of the player; the right-hand pedal was to raise a hinged portion of the top or cover and thus gain some power of "swell" or crescendo, an invention of Roger Plenius, to whom also the harp stop may be rightly attributed. This ingenious harpsichord maker had been stimulated to gain these effects by the nascent pianoforte which, as we shall find, he was the first to make in England. The first idea of pedals for the harpsichord to act as stops appears to have been John Hayward's (? Haward) as early as 1676, as we learn from Mace's *Musick's Monument*. The French makers preferred a kind of knee-pedal arrangement known as the "genouillère," and sometimes a more complete muting by one long strip of buff leather, the "sourdine." As an improvement upon Plenius's clumsy swell, Shudi in 1769 patented the Venetian swell, a framing of louvres, like a Venetian blind, which opened by the movement of the pedal, and, becoming in England a favourite addition to harpsichords, was early transferred to the organ, in which it replaced the rude "nag's-head" swell. A French harpsichord maker, Marius, whose name is remembered from a futile attempt to design a pianoforte action, invented a folding harpsichord, the "clavecin brisé," by which the instrument could be disposed of in a smaller space. One, which is preserved at Berlin, probably formed part of the camp baggage of Frederick the Great.

It was formerly a custom with kings, princes, and nobles who were well-disposed towards music to keep large collections of musical instruments,—not as now for beauty of decoration, form, and colour, or historical associations, but for actual playing purposes in the domestic and festive music of their courts. There are records of their inventories, and it was to keep such a collection in playing order that Prince Ferdinand dei Medici engaged a Paduan harpsichord maker, Bartolommeo Cristofori, the man of genius who invented and produced the pianoforte. We fortunately possess the record of this invention in a literary form from a well-known writer, the Marchese Scipione Maffei; his description appeared in the *Giornale dei letterati d'Italia*,

a publication conducted by Apostolo Zeno. The date of Maffei's paper was 1711. Rimbault reproduced it, with a technically imperfect translation, in his *History of the Piano-forte*. We learn from it that in 1709 Cristofori had completed four "gravecembali col piano e forte"—keyed-psalteries with soft and loud—three of them being of the long or usual harpsichord form. A synonym in Italian for the original cembalo (or psaltery) is "salterio," and if it were struck with hammers it became a "salterio tedesco" (the German *hackbrett*, or chopping board), the latter being the common dulcimer. Now the first notion of a pianoforte is a dulcimer with keys, and we may perhaps not be wrong in supposing that there had been many attempts and failures to put a keyboard to a dulcimer or hammers to a harpsichord before Cristofori successfully solved the problem. The sketch of his action in Maffei's essay shows an incomplete stage in the invention, although the kernel of it, the principle of escapement or the controlled rebound of the hammer, is already there. He obtains it by a centred lever (*linguetta mobile*) or hopper, working, when the key is depressed by the touch, in a small projection from the centred hammer butt. The return, governed by a spring, must have been uncertain and incapable of further regulating than could be obtained by modifying the strength of the spring. Moreover, the hammer had each time to be raised the entire distance of its fall. There are, however, two pianofortes by Cristofori in Florence, dated respectively 1720 and 1726, which show a much improved, we may even say a perfected, construction, for the whole of an essential piano movement is there. The earlier instrument has undergone some restoration, but the 1726 one, which is in the Kraus Museum, retains the original leather hammerheads. Both instruments possess alike a contrivance for determining the radius of the hopper, and both have been unexpectedly found to have the "check" (Ital. *paramartello*) which regulates the fall of the hammer according to the strength of the blow which has impelled it to the strings. After this discovery of the actual instruments of Cristofori, there can be no longer doubt as to the attribution of the invention to him, in its initiation and its practical completion with escapement and check. To Cristofori we are indebted not only for the power of playing *piano* and *forte*, but for the infinite variations of tone, or *nuances*, which render the instrument so delightful.

But his problem was not solved by the devising of a working action; there was much more to be done to instal the pianoforte as a new musical instrument. The reson-

FIG. 13.—Cristofori's Escapement Action, 1720.

ance, that most subtle and yet all-embracing factor, had been experimentally developed to a certain perfection by many generations of spinet and harpsichord makers, but the resistance structure had to be thought out again. Thicker stringing, rendered indispensable to withstand even Cristofori's light hammers, demanded, in its turn, a stronger framing than the harpsichord had needed. To make his structure firm, he considerably increased the strength of the block which holds the tuning-pins, and, as he could not do so without materially adding to its thick-

ness, he adopted the bold expedient of inverting it, driving his wrest-pins, harp-fashion, through it, so that tuning was effected at their upper, while the wires were attached to their lower ends.

Then to guarantee the security of the case he ran an independent string-block round it of stouter wood than had been used in harpsichords, in which block the hitch-pins were driven to hold the farther ends of the strings, which were spaced at equal distances (unlike the harpsichord), the dampers lying between the pairs of unisons.

Cristofori died in 1731. He had pupils, but did not found a school of Italian

pianoforte making, perhaps from the peculiar Italian conservatism in musical instruments we have already remarked upon.

The essay of Scipione Maffei was translated into German in 1725, by König, the court poet at Dresden, and friend of Gottfried Silbermann, the renowned organ builder and harpsichord and clavichord maker.<sup>1</sup> Incited by this publication, and perhaps by having seen in Dresden one of Cristofori's pianofortes, Silbermann appears to have taken up the new instrument, and in 1726 to have manufactured two, which J. S. Bach, according to his pupil Agricola, pronounced failures. The trebles were too weak; the touch was too heavy. There has long been another version to this story, viz., that Silbermann borrowed the idea of his action from a very simple model contrived by a young musician named Schroeter, who had left it at the electoral court in 1721, and, quitting Saxony to travel, had not afterwards claimed it. It may be so; but Schroeter's letter, printed in Mitzler's *Bibliothek*, dated 1738, is not supported by any other evidence than the recent discovery of an altered German harpsichord, the hammer action of which, in its simplicity, may have been taken from Schroeter's diagram, and would sufficiently account for the condemnation of Silbermann's earliest pianofortes if he had made use of it. In either case it is easy to distinguish between the lines of Schroeter's interesting communications (to Mitzler and later to Marburg) the bitter disappointment he felt in being left out of the practical development of so important an instrument.

But, whatever Silbermann's first experiments were based upon, it has been made certain by the personal investigations of the present writer that he, when successful, adopted Cristofori's pianoforte without further alteration than the compass and colour of the keys, and the style of joinery of the case. In the Silbermann grand pianofortes, in the three palaces at Potsdam, known to have been Frederick the Great's, and to have been acquired by that monarch prior to J. S. Bach's visit to him in 1747, we find the Cristofori framing, stringing, inverted wrest-plank, and action complete. Fig. 15 represents the instrument on which J. S. Bach played in the Town Palace, Potsdam.

It has been repeatedly stated in Germany that Frederici of Gera in Saxony, an organ builder and musical instrument

FIG. 14.—Cristofori's Piano e Forte, 1726; Kraus Museum Florence.

<sup>1</sup> This translation, reproduced *in extenso*, may be read in Dr Oscar Paul's *Geschichte des Claviers*, Leipzig, 1868.

maker, invented the square or table-shaped piano, the "fort bien" as he is said to have called it, about 1758-60. No square piano by this maker is forthcoming, but M. Victor

do with the invention of it<sup>1</sup>) a square piano, which was to become the most popular domestic instrument. Burney tells us all about Zumpo; and his instruments, still existing, fix the date of the first at about 1765. In his simple "old man's head" action, we have the nearest approach to a realization of Schroeter's simple idea. It will be observed that Schroeter's damper would stop all vibration at once. This defect is overcome by Zumpo's "mopstick" damper.

Another piano action had, however, come into use about that time or even earlier in Germany. The discovery of it in the simplest form is to be attributed to M. Mahillon, who has found it in a square piano belonging to M. Henri Gosselin, painter, of Brussels. The principle of this action is that which was later perfected by the addition of a good escapement by Stein of Augsburg, and was again later experimented upon by Sebastian Erard. Its origin is perhaps due to the contrivance of a piano action that should suit the shallow clavichord and

Fig. 15.—Silbermann Forte Piano; Stadtschloss, Potsdam, 1746. Engraved by permission of H.L.H. the Crown Princess of Prussia.

Mahillon of Brussels has acquired a Frederici "upright grand" piano, dated 1745, and contributes a diagram of the simple action (fig. 16). In Frederici's upright grand action we have not to do with the ideas of either Cristofori or Schroeter; the movement is practically identical with the hammer action of a German clock, and has its counterpart in a piano at Nuremberg, a fact which needs further elucidation. We note here the earliest example of the leather hinge afterwards so common in piano actions, and only now going out of use. Where are we to look for Schroeter's copyist, if not found in Silbermann, Frederici, or, as we shall presently see, perhaps Wagner? It might be in the harpsichord we have mentioned, which, made in 1712 by one Brock for the elector of Hanover (afterwards George I. of England), was by him presented to

Fig. 16.—Frederici's Upright Grand Piano Action, 1745. Instrument now transferred to the museum of the Brussels Conservatoire.

the Protestant pastor of Schulenberg near Hanover, and has since been rudely altered into a pianoforte (fig. 17). There is an altered harpsichord in the museum at Basel which appears to have been no more successful. But an attempted combination of harpsichord and pianoforte appears as a very early intention. The English poet Mason, the friend of Gray, bought such an

Fig. 17.—Hammer and Lifter of altered Harpsichord by Brock. Instrument in the collection of Mr Kendrick Pyne, Manchester.

instrument at Hamburg in 1755, with "the cleverest mechanism imaginable."

It was only under date of 1763 that Schroeter published for the first time a diagram of his proposed invention, designed more than forty years before. It appeared in Marburg's *Kritische Briefe* (Berlin, 1764). Now, immediately after, Johann Zumpo, a German in London who had been one of Shudi's workmen, invented or introduced (for there is some tradition that Mason had to

Fig. 18.—Schroeter's Model for an Action, 1721.

permit of its transformation into a square piano; a transformation, Schroeter tells us, had been going on when he

Fig. 19.—Zumpo's Square Piano Action, 1766.

wrote his complaint. It will be observed that the hammer is, as compared with other actions, reversed, and the axis

Fig. 20.—Old Piano Action on the German principle of Escapement. Square Piano belonging to M. Gosselin, Brussels.

rises with the key, necessitating a fixed means for raising the hammer, in this action effected by a rail against which the hammer is jerked up. It was Stein's merit to graft the hopper principle upon this simple action; and Mozart's

<sup>1</sup> Mason really invented the "celestina," as we know from the correspondence of Mary Granville. Under date of the 11th January 1775 she describes this invention or improvement of the poet as a short harpsichord in form, 2 feet long, but played with the right hand only. The left hand controlled a kind of violin-bow, which produced a charming *sostinente*, in character of tone between the violin tone and that of musical glasses. Mason played upon it with great expression.

approbation of the invention, when he met with it at Augsburg in 1777, is expressed in a well-known letter addressed to his mother. No more "blocking" of the hammer, destroying all vibration, was henceforth to vex his mind.

FIG. 21.—Stein's Action (the earliest so-called Viennese). 1780.

He had found the instrument that for the rest of his short life replaced the harpsichord. M. Mahillon has secured for his museum the only Johann Andreas Stein piano which is known to remain. It is from Augsburg, dated 1780, and has Stein's escapement action, two unisons, and the knee pedal, then and later common in Germany.

Mozart's own grand piano, preserved at Salzburg, and the two grand pianos (the latest dated 1790) by Huhn of Berlin, preserved at Berlin and Charlottenburg, because they had belonged to the Prussian Queen Louise, follow Stein in all particulars. These instruments have three unisons upwards, and the muting movement known as *celeste*, which no doubt Stein had also. The wrest-plank is not inverted; nor is there any imitation of Cristofori. We may regard Stein, coming after the Seven Years' War which had devastated Saxony, as the German reinventor of the grand piano. Stein's instrument was accepted as a model, as we have seen, in Berlin as well as Vienna, to which city his business was transferred in 1794 by his daughter Nanette, known as an accomplished pianist and friend of Beethoven, who at that time used Stein's pianos. She had her brother in the business with her, and had already, in 1793, married J. A. Streicher, a pianist from Stuttgart, and distinguished as a personal friend of Schiller. In 1802, the brother and sister dissolving partnership, Streicher began himself to take his full share of the work, and on Stein's lines improved the Viennese instrument, so popular for many years and famous for its lightness of touch, which contributed to the special character of the Viennese school of pianoforte playing. The firm of Streicher still exists in Vienna; but since 1862, when Steinway's example caused a complete revolution in German and Austrian piano-making, the old wooden cheap grand piano has died out. We will quit the early German piano with an illustration (fig. 22) of an early square piano action in an instrument

FIG. 22.—German Square Action, 1783. Piano by Wagner, Dresden.

made by Johann Gottlob Wagner of Dresden in 1783. This interesting discovery of M. Mahillon's introduces us to a rude imitation (in the principle) of Cristofori, and it appears to have no relation whatever to the clock hammer notion seen in Frederici's.

Burney, who lived through the period of the displacement of the harpsichord by the pianoforte, is the only authority we can refer to as to the introduction of the latter instrument into England. He tells us,<sup>1</sup> in his gossiping way, that the first hammer harpsichord that came to England was made by an English monk at Rome, a

<sup>1</sup> Rees's *New Cyclopædia*, article "Harpsichord."

Father Wood, for an English gentleman, Samuel Crisp of Chesington; the tone of this instrument was superior to that produced by quills, with the added power of the shades of *piano* and *forte*, so that, although the touch and mechanism were so imperfect that nothing quick could be executed upon it, yet in a slow movement like the Dead March in Saul it excited wonder and delight. Fulke Greville afterwards bought this instrument for 100 guineas, and it remained unique in England for several years, until Plenius, the inventor of the lyrichord, made a pianoforte in imitation of it. In this instrument the touch was better, but the tone was inferior. We have no date for Father Wood. Plenius produced his lyrichord, a *sostinente* harpsichord, in 1745. When Mason imported a pianoforte in 1755, Fulke Greville's could have been no longer unique. The Italian origin of Father Wood's piano points to a copy of Cristofori, but the description of its capabilities in no way supports this supposition, unless we adopt the very possible theory that the instrument had arrived out of order and there was no one in London who could put it right, or would perhaps divine that it was wrong. Burney further tells us that the arrival in London of J. C. Bach in 1759 was the motive for several of the second-rate harpsichord makers trying to make pianofortes, but with no particular success. Of these Americus Backers, said to be a Dutchman, appears to have gained the first place. He was afterwards the inventor of the so-called English action, and, as this action is based upon Cristofori's, we may suppose he at first followed Silbermann in copying the original inventor. There is an old play-bill of Covent Garden in Messrs Broadwood's possession, dated the 16th May 1767, which has the following announcement:—

"End of Act 1. Miss BRICKLER will sing a favourite song from JUDITH, accompanied by Mr DIBDIN, on a new instrument call'd PIANO FORTE."

The mind at once reverts to Backers as the probable maker of this novelty. Be that as it may, between 1772 and 1776, the year of his death, he produced the action continued in the direct principle to this day by the firm of Broadwood, or with a reversed lever and hammer-butt introduced by the firm of Collard in 1835.

Fig. 23.—Grand Piano Action, 1776. The "English" action of Americus Backers.

The escapement lever is suggested by Cristofori's first action, to which Backers has added a contrivance for regulating it by means of a button and screw. The check is from Cristofori's second action. No more durable action has been constructed, and it has always been found equal, whether made in England or abroad, to the demands of the most advanced virtuosi. John Broadwood and Robert Stodart were friends, Stodart having been Broadwood's pupil; and they were the assistants of Backers in the

he was certainly engaged upon the elementary action described as appertaining to M. Gosselin's piano, of probably German origin. In his long-continued labour of inventing and constructing a double escapement action, Erard appears to have sought to combine the English power of gradation of tone with the German lightness of touch. He took out his first patent for a "repetition" action in 1808, claiming for it "the power of giving repeated strokes without missing or failure, by very small angular motions of the key itself." He did not, however, succeed in producing his famous repetition, or double escapement action until 1821; it was then patented by his nephew Pierre Erard, who, when the patent expired in England in 1835, proved a loss from the difficulties of carrying out the invention, which induced the House of Lords to grant an extension of the patent.

Although some great pianists have been opposed to double escapement, notably Kalkbrenner, Chopin, and Dr Hans von Bülow, Erard's action, in its complete or a shortened form as introduced by Herz, is now more extensively used than at any former period. Erard invented in

FIG. 27.—Steinway's Grand Piano Action, 1884. The double escapement as in Erard's, but with shortened balance and usual check.

1808 an upward bearing to the wrest-plank bridge, by means of agraffes or studs of metal through holes in which the strings are made to pass, bearing against the upper side. The wooden bridge with down-bearing strings is clearly not in relation with upward-striking hammers, the tendency of which must be to raise the strings from the bridge, to the detriment of the tone. A long brass bridge on this principle was introduced by William Stodart in 1822. A pressure-bar bearing of later introduction is claimed for the French maker, M. Bord, and is very frequently employed, by German makers especially. The first to see the importance of iron sharing with wood (ultimately almost supplanting it) in pianoforte framing was a native of England and a civil engineer by profession, John Isaac Hawkins, who has been best known as the inventor of the ever-pointed pencil. He was living at Philadelphia, U.S., when he invented and first produced the familiar cottage pianoforte—"portable grand" as he then called it. He patented it in America, his father, Isaac Hawkins, taking out the patent for him in England in the same year, 1800. It will be observed that the illustration here given (fig. 28) represents a wreck; but a draughtsman's restoration might be open to question.

There had been upright grand pianos as well as upright harpsichords, the horizontal instrument being turned up upon its wider end and a keyboard and action adapted to it. William Southwell, an Irish pianomaker, had, in 1798, tried a similar experiment with a square piano, to be repeated in later years by W. F. Collard of London; but Hawkins was the first to make a piano, or pianino, with the strings descending to the floor, the keyboard being raised, and this, although at the moment the chief, was not his only merit. He anticipated nearly every discovery that has since been introduced as novel. His instrument is in a complete iron frame, independent

of the case; and in this frame, strengthened by a system of iron resistance rods combined with an iron upper bridge, his sound-board is entirely suspended. An apparatus for

FIG. 28.—Hawkins's Portable Grand Piano, 1800. An upright instrument, the original of the modern cottage piano or pianino. In Messrs Broadwood's museum and unrestored.

tuning by mechanical screws regulates the tension of the strings, which are of equal length throughout. The action, in metal supports, anticipates Wornum's in the checking, and still later ideas in a contrivance for repetition. This remarkable bundle of inventions was brought to London and exhibited by Hawkins himself, but the instrument being poor in the tone failed to bring him pecuniary reward or the credit he deserved. Southwell appears to have been one of the first to profit by Hawkins's ideas by bringing out the high cabinet pianoforte, with hinged sticker action, in 1807. All that he could, however, patent in it was the simple damper action, turning on a pivot to relieve the dampers from the strings, which is still frequently used with such actions. The next steps for producing the lower or cottage upright piano were taken by Robert Wornum, who in 1811 produced a diagonally and in 1813 a vertically strung one. Wornum's perfected crank action was not complete until 1826, when it was patented for a cabinet piano; but it was not really introduced until three years later, when Wornum applied it to his little "piccolo." The principle of this centred lever check action was introduced into Paris by Pleyel<sup>1</sup> and Pape, and thence has gone to Germany and America. In England it has now nearly superseded the once favourite leather-hinged action.

It was not, however, from Hawkins's invention that iron became introduced as essential to the structure of a pianoforte. This was due to William Allen, a young Scotsman in the employ of the Stodarts. He devised a metal system of framing intended primarily for compensation, but soon to become, in other hands, a framing for resistance. His idea was to meet the divergence in tuning caused in brass and iron strings by

<sup>1</sup> Pleyel exhibited a small upright piano in Paris in 1827. Pierre Erard did not turn his attention to upright pianos until 1831.

atmospheric changes by compensating tubes and plates of the same metals, guaranteeing their stability by a cross batoning of stout wooden bars and a metal bar across the wrest-plank. Allen, being simply a tuner, had not the full practical knowledge for carrying out the idea. He had to ally himself with Stodarts' foreman, Thom; and Allen and Thom patented the invention in January 1820. The firm of Stodart at once acquired the patent. We have now arrived at an important epoch in pianoforte construction,—the abolition, at least in England and France, of the wooden construction in favour of a combined construction of iron and wood, the former material gradually asserting pre-eminence. Allen's design is shown in fig. 30. The long bars shown in the diagram are really tubes fixed at one end only; those of iron lie over the iron or steel wire, while those of brass lie over the brass wire, the metal plates to which they are attached being in the same correspondence. At once a great advance was made in the possibility of using heavier strings than could be stretched before, without danger to the durability of the case and frame. The next step was in 1821 to a fixed iron string-plate, the invention of one of Broadwood's workmen, Samuel Hervé, which was in the first instance applied to one of the square pianos of that firm. The great advantage in the fixed plate was a more even

FIG. 30.—Allen's Compensating Grand Piano, 1820. The first complete metal framing system applied over the strings.

drawing or tension of the strings and the abolition of their undue length behind the bridge, a reduction which Isaac Carter<sup>1</sup> had tried some years before, but unsuccessfully, to accomplish with a plate of wood. So generally was attention now given to improved methods of resistance that it has not been found possible to determine who first practically introduced those long iron or steel resistance bars which are so familiar a feature in modern grand pianos. They were experimented on as substitutes for the wooden bracing by Joseph Smith in 1798; but to James Broadwood belongs the credit of trying them first above the sound-board in the treble part of the scale as long ago as 1808, and again in 1818; he did not succeed, however, in fixing them properly. The introduction of fixed resistance bars is really due to observation of Allen's compensating tubes, which were, at the same time, resisting. Sebastian and Pierre Erard seem to have been first in the field in 1823 with a complete system of nine resistance bars from treble to bass, with a simple mode of fastening them through the sound-board to the wooden beams beneath, but, although these bars appear in their patent of 1824, which chiefly concerned their repetition action, the Erards did not either in France or England claim them as of original invention, nor is there any string-plate combined

<sup>1</sup> Sometime foreman to the pianoforte maker Mott, who attracted much attention by a piano with sostenente effect, produced by a roller and silk attachments in 1817. But a sostenente piano, however perfect, is no longer a true piano such as Beethoven and Chopin wrote for.

with them in their patent. James Broadwood, by his patent of 1827, claimed the combination of string-plate and resistance bars, which was clearly the completion of the wood and metal instrument, differing from Allen's in the nature of the resistance being fixed. Broadwood, however, left the bass bars out, but added a fourth bar in the middle to the three in the treble he had previously used. It must be borne in mind that it was the trebles that gave way in the old wooden construction before the tenor and bass of the instrument. But the weight of the stringing was always increasing, and a heavy close overspinning of the bass strings had become general. The resistance bars were increased to five, six, seven, eight, and, as we have seen, even nine, according to the ideas of the different English and French makers who used them in their pursuit of stability.

The next important addition to the grand piano in order of time was the harmonic bar of Pierre Erard, introduced in 1838. This was a gun-metal bar of alternate pressing and drawing power by means of screws which were tapped into the wrest-plank immediately above the treble bearings; making that part of the instrument nearly immovable, this favoured the production of higher harmonics to the treble notes, recognized in what we commonly call "ring." A similar bar, subsequently extended by Broadwood across the entire wrest-plank, was to prevent any tendency in the wrest-plank to rise, from the combined upward drawing of the strings. A method of fastening the strings on the string-plate depending upon friction, and thus dispensing with "eyes," was a contribution of the Collards, who had retained James Stewart, who had been in America with Chickering, and was a man of considerable inventive power. This invention was introduced in 1827. Between 1847 and 1849 Mr Henry Fowler Broadwood, son of James, and grandson of John Broadwood, and also great grandson of Shudi ('Tschudi'), invented a grand piano-forte to depend practically upon iron, in which, to avoid the conspicuous inequalities caused by the breaking of the scale with resistance bars, there should be no bar parallel to the strings except a bass bar, while another flanged resistance bar, as an entirely novel feature, crossed over the strings from the bass corner of the wrest-plank to a point upon the string-plate where the greatest accumulation of tension strain was found. Mr Broadwood has

FIG. 31.—Broadwood's Iron Grand Piano, 1834. Complete iron frame with diagonal resistance bar.

not continued, without some compromise, this extreme renunciation of ordinary resistance means. Since the Great Exhibition of 1851 he has employed an ordinary straight bar in the middle of his concert grand scale, his smaller grands having frequently two such as well as the long bass bar. From 1862 he has covered his wrest-plank with a thick plate of iron into

which the tuning pins screw as well as into the wood beneath, thus avoiding the crushing of the wood by the constant pressure of the pin across the pull of the string, an ultimate source of danger to durability.

The introduction of iron into pianoforte structure has been differently and independently effected in America, the fundamental idea there being a single casting for the metal plate and bars, instead of forging or casting them in separate pieces. Alphaus Babcock was the pioneer to this kind of metal construction. He also was bitten with the compensation notion, and had cast an iron ring for a square piano in 1825, which is not said to have succeeded, but gave the clew to a single casting resistance framing, which was successfully accomplished by Conrad Meyer, in Philadelphia, in 1833, in a square piano which still exists, and was shown in the Paris Exhibition of 1878. Meyer's idea was taken up and improved upon by Jonas Chickering of Boston, who applied it to the grand piano as well as to the square, and brought the principle up to a high degree of perfection,—establishing by it the independent construction of the American pianoforte.

We have now to do with over- or cross-stringing, by which the bass division of the strings is made to cross over the tenor part of the scale in a single, double, or treble disposition at diverging angles,—the object being in the first instance to get longer bass strings than are attainable in a parallel scale, and in the next to open out the scale and extend the area of bridge pressure on the sound-board. In the 18th century clavi-chords were sometimes overstrung in the lowest octave to get a clearer tone in that very indistinct part of the instrument (strings tuned an octave higher being employed). The first suggestion for the overstringing in the piano was made by the celebrated flute-player and inventor Theobald Boehm, who carried it beyond theory in London, in 1831, by employing a small firm located in Cheapside, Geroock & Wolf, to make some overstrung pianos for him. Boehm expected to gain in tone; Pape, an ingenious mechanic in Paris, tried a like experiment to gain economy in dimensions, his notion being to supply the best piano possible with the least outlay of means. Tomkinson in London continued Pape's model, but neither Boehm's nor Pape's took permanent root. The Great Exhibition of 1851 contained a grand piano, made by Lichtenthal of St Petersburg, overstrung in order to gain symmetry by two angle sides to the case. It was regarded as a curiosity only. A few years later, in 1855, Henry Engelhard Steinway (originally Steinweg), who had emigrated from Brunswick to New York in 1849, and had established the firm of Steinway & Sons in 1853 in that city, effected the combination of an overstrung scale with the American iron frame, which, exhibited in grand and square instruments shown in London in the International Exhibition of 1862, excited the attention of European pianoforte makers, leading ultimately to important results. The Chickering firm claim to have anticipated the Steinways in this invention. They assert that Jonas Chickering had begun a square piano on this combined system in 1853, but, he dying before it was completed, it was brought out later. It is often difficult to adjudicate

FIG. 32.—Meyer's Metal Frame for a Square Piano, 1833. In a single casting.

upon the claims of inventors, so rarely is an invention the product of one man's mind alone. However, the principle has been taken up and generally adopted in America and Germany, and has found followers elsewhere, not only in grand but in upright pianos, to the manufacture of which it has given, and particularly in Germany, a powerful impetus. But, in spite of this general recognition, the overstringing, as at present effected, is attended with grave disadvantages, in disturbing the balance of tone by introducing thick, heavy basses, which, like the modern pedal organs, bear no just relation to that part of the keyboard where the part-writing lies. The great increase

also of tension which is held up as a gain, acts prejudicially upon the durability of the instrument, as no artificial screwing up of the sound-board can always preserve the elasticity of the fibres of the fir tree (*Abies excelsa* in Europe, *Abies alba* in America) of which it is made. The remarkable improvements in the drawing of the cast steel wire produced in Birmingham, Vienna, and Nuremberg (this last initiated by Bochum) have rendered very high tensions practicable. We believe

FIG. 33.—Steinway's Grand Piano, 1854. Metal framing in a single casting and overstrung.

they have been overstated in figures; it is certain, however, that Broadwood's seven-octave concert grands have a tension of not less than sixteen tons when at the English orchestral pitch,—the notes of the ideal lengths each drawing 450 lb. We have no such accurate statement to offer of the American and German concert grands, but we regard Steinway's as of not less than twenty-two tons tension.

Whatever of importance has been introduced in the structure of the pianoforte we believe we have attributed to its legitimate inventor or to the manufacturer who has placed it in the light of day. It would be impossible within reasonable limits to chronicle the variations which have taken place in the barrings of sound-boards on which their resonant structure depends, the disposition of wooden beams or metal bars, the adaptation of mechanical action, or any of those countless modifications upon which finally depends the individual character of an instrument worthy to be presented and upheld as a work of art. There are many names of first-rate pianoforte makers whose place has not been in this record, simply because they have not ranked with the initiators or perfecters of inventions that have been accepted as of paramount importance.

The earliest keyboard instrument makers were to be found in monasteries or collegiate foundations, and such lay help as may have been employed was at best of the roughest kind. In the next epoch the artists' guilds in cities absorbed lay musical instrument makers, notably on account of the then universal practice of making such instruments beautiful; and, indeed, we are indebted to this for the preservation of many spinets and harpsichords in museums and private collections. The full members of the craft-

guilds were all masters who had terminated their apprenticeships by producing complete instruments as "master-pieces," made according to the rules and to the satisfaction of the wardens or deacons of the guilds. A trial of this kind lasted long in many crafts—for instance, in the case of Scottish cabinetmakers' indentures, an apprentice's freedom was only gained after the test production of an "essay" piece of work, duly authenticated and admitted. Spinets and harpsichords were bound to bear the inscription of the maker's name, or to show his trade mark as a guarantee for honest workmanship. The master's sons and apprentices were, in the master's workshops, probationers of the guild and protected by it. Even in the 17th century we hear little about journeymen, who, as the name implies, would be paid by the day. But the extension of musical instrument workshops about the beginning of the 18th century was one of the signs of the weakened power of the guilds—particularly in Great Britain. In France it needed the Revolution to entirely abolish them.

Throughout the 18th century journeywork and apprenticeship were general. Wages, compared with the cost of living, were meagre, and the day's work, not unfrequently extended by overtime, was a long one. The result was a slow production. The English cabinet-makers, however, owing to disputes which at last called for judicial interference, in the year 1738 brought out their book of prices which was the foundation of the present piece-work system. Pianoforte makers in course of time adopted this new departure with the result of quicker work and higher wages, benefiting alike the master and man. The next industrial revolution was inaugurated somewhere about 1815, by the introduction of machinery to save manual labour, the division of which had already been instituted, and by the use of steam. Machinery has, as yet, been extended to its furthest limit in America, where labour-saving is relied upon as a powerful ally against strikes, which are more frequently victorious in the New than in the Old World. Simultaneously a dislike has arisen to apprenticeships; and even in Germany, the traditional land of the apprentice, this mode of acquirement has weakened.

Turning to the commercial importance of the pianoforte, we find that we have to face great difficulties in order to obtain anything like trustworthy information. It is true official blue-books give yearly statements of exports and imports, but as they do not separate the pianoforte from other musical instruments an analysis is impossible. Personal inquiry again among pianoforte makers brings but scattered information, partly from the natural inclination to enhance business returns, and partly from an equally natural disinclination to impart that which, if spoken of at all, should be confidential. From this dilemma we fall back upon gleanings of intelligence either of our own gathering or as afforded by the leading pianoforte trade organs in England and Germany—the *London Music Trades Review* and the *Leipziger Zeitschrift für Instrumentenbau*.

The chief centres of the pianoforte trade are London, Paris, Berlin, Leipzig, Dresden, Stuttgart, Hamburg, Vienna, St Petersburg, Brussels, New York, Boston, and Baltimore. The greatest centralizations are found in London and Paris,—very few pianofortes being made in the United Kingdom or France, excepting perhaps at Marseilles, out of those cities. But in Germany and the United States there are pianoforte makers in many towns besides those we have named. Pianofortes are made in Italy at Turin, Milan, Florence, Naples, and Palermo, and in Spain at Barcelona (principally), Madrid, and Saragossa. The large export trade belonged formerly to England and France, but it has been weakened of late years by the commercial activity of the Germans, who have besides copied successfully and with the advantage of much lower wages recent American models. German pianofortes are now much found in Great Britain, where free trade has favoured their introduction, and in the Australian colonies; they have also outvalued the French in Holland; but we believe France still keeps the trade of southern Europe, as the United States mainly supply Canada. English exports of good makers will be found all over the world; but some important markets have been lost through the inferior instruments consigned or sold because they were cheap, and were supposed to be good enough.

The United States and Germany appear to employ the greatest number of workmen in the pianoforte handicraft, Germany producing the largest numbers of instruments. In adopting, however, the statistics given, we must not forget to take into account that custom of advertising which leavens nearly every statement. There are said to be upwards of 8000 workmen employed in piano-making in America. The Messrs Steinway claim for America an annual production of 25,000 pianofortes of all kinds, and it may be more. We hardly feel disposed to allow Germany 73,000, with put forward by a semi-official source, the *Deutsche Consulats-Zeitung*. It must be borne in mind that machinery adds its power indefinitely to the number of men employed, but this occurs more so in America than in Germany. A recent strike in Paris represented the pianoforte trade society as consisting of 5000 members; and we may safely credit that city with a production of 20,000 instruments yearly. The number made in London annually may be taken as reaching at least 33,000; it is probably larger.

PIARISTS, the popular name of the "clerici regulares scholarum piarum," the Pauline Congregation of the Mother of God, which was founded by Joseph Calasanza (Josephus a Matre Dei) at Rome in the beginning of the 17th century. Calasanza, a native of Calasanz in the province of Huesca in Aragon, was born on September 11, 1556, studied at Lerida and Alcala, and after his ordination to the priesthood removed to Rome. Here he became zealously interested in the education of poor and orphan children, and with this end he organized, in 1607, a brotherhood which ultimately, in 1617, became an independent Congregation, numbering at that time fifteen priests, under Calasanza as their head. To the three usual vows they added a fourth, that of devotion to the gratuitous instruction of youth. In 1622 the Congregation received a new constitution from Gregory XV., and had all the privileges of the mendicant orders conferred upon it, Calasanza being recognized as general. In this capacity he busied himself with the extension of the order, not only in Italy, but also in Germany, Poland, and other countries, until 1643, when the jealousy of the Jesuits led to conflicts which resulted in his removal from office; owing to the same cause the Congregation was deprived of its privileges by Innocent X. in 1646. Calasanza, who died on August 22, 1648, was beatified in 1748, and canonized in 1767. The privileges of the Congregation were successively restored in 1660, 1669, and 1698. The Piarists, who are not a numerous body, are found chiefly in Italy, Spain, the West Indies, Germany, and especially in Austria-Hungary.

PIATRA, a town of Roumania (Moldavia) at the head of the department of Neamtso, on the left bank of the Bistritza, an affluent of the Sereth. It is about 45 miles

by road from Roman, a station on the railway from Galatz and Czernowitz. The population of the prefecture in 1878 was 25,383 (9887 Jews). It contained seven Orthodox churches,—the most remarkable being St John's, or the Prince's Monastery, founded by Stephen the Great in 1497. There are five annual fairs, and a large trade is done in grain and timber—the latter being rafted down the Bistritza from the mountains to Galatz.

**PIAZZA ARMERINA** (Sicilian, *Chiazza*), a city of Italy, in the province of Caltanissetta, Sicily, on a hill 39 miles by road east-south-east of the city of that name, and 30 miles north of Terranova on the coast. It is a flourishing and populous place (17,038 inhabitants in the city and 19,591 in the commune in 1881), has an 18th-century cathedral, an episcopal palace, and a communal library (1859). The church of Sant' Andrea, less than a mile distant, has a fresco of date 1486, and other objects of interest.

Of the ancient city, which old local antiquaries held to have been built by a colony of refugees from Plataea, little is known. The name sometimes occurs as Plutia. In 1095 Piazza was taken by Count Roger of Sicily, who bestowed on it a banner reputed to bear a likeness of the Virgin painted by St Luke. William I. destroyed the city in 1160, but it was rebuilt on a new site in 1163.

See *Piazza antica*, &c., by J. P. Chiaranda (a native), of which a Latin translation by Mosheim is given in Grævius's *Thesaurus ant. et hist. Sic.*, vol. xii.

**PIAZZI, GIUSEPPE** (1746–1826). See **ASTRONOMY**.

**PICARDY** (*La Picardie*), one of the old fental provinces of France, was bounded N. by Hainault, Artois, and the English Channel, E. by Champagne, S. by Île-de-France, and W. by Normandy and the Channel. Northern Picardy (subdivided into Upper and Lower Picardy) was formed into one of the great military governorships of the kingdom, while Southern Picardy was included in the governorship of Île-de-France. Upper Picardy comprised the districts (*pays*) of Amienois, Santerre, Vermandois, and Thierache; Lower Picardy Boulonnais, Ponthieu, Vimeu, and the Pays Reconquis (or Calais, Guines, Ardre, and Oye); and Southern Picardy Beauvaisis, Soissonais, and Laonnais. The territory is now divided among the departments of Pas-de-Calais, Somme, Aisne, Oise, and Nord.

The name Picardy does not appear before the 13th century. Under the Romans the country formed part of Belgica Secunda, and was inhabited by various Belgian tribes—the Morini, Ambiani, Veromandui, Bellovaci, and Suessiones, whose names still appear in Amiens, Vermandois, Beauvais, and Soissons. After forming part of the kingdom of Soissons and of Neustria, Picardy (that is, the countship of Vermandois, &c.) passed to the counts of Flanders. It was finally united with the French crown by Louis XI.

See *De Verité* (1770–74), Dubelloy (1770), La Bourc (1840), Roger (1842–43), and Cocheris (1851). V. de Beauville has published a magnificent *Recueil de documents inédits concernant la Picardie*, 1861, 1867, &c.

**PICCINI, or PICCINI, NICCOLA** (1728–1800), musical composer, was born at Bari in 1728, and educated, under Leo and Durante, at the Conservatorio di San Onofrio in Naples. His first opera, *Le Donne dispettose*, produced in 1754, won him a high reputation, which he maintained creditably until 1760, when he composed, at Rome, the *chef d'œuvre* of his early life, *La Cecchina, ossia la Buona Figliuola*, an *opera buffa* which attained a European success, little less remarkable than that of Pergolesi's *Serva Padrona*. In a very short time this charming piece found its way not only to every theatre in Italy, but to Paris, to London, and to every great city on the Continent. It was even represented by marionettes; and every new fashion was named *alla Cecchina*. Six years after this Piccini was invited to Paris. He knew nothing of French, but his librettist, Marmontel, assisted him to such good purpose that, after the production of his first French opera, *Roland*, he was carried home from the theatre in triumph. All his next works were successful; but, unhappily, the directors of the Grand Opéra conceived the mad idea of deliberately opposing him to Gluck, by persuading the two composers to treat the same subject—*Iphigénie en Tauride*—simultaneously. The Parisian public now divided itself into two rival parties,

which, under the names of Gluckists and Piccinists, carried on an unworthy and disgraceful war, equally ruinous to both artists, who would gladly have withdrawn from its violent excesses. That the final victory should be obtained by the Gluckists was inevitable; for Piccini, though a brilliant ornament of the Italian school, was no match for his illustrious antagonist. Gluck's masterly *Iphigénie* was first produced on May 18, 1779. Piccini's *Iphigénie* followed on January 23, 1781, and, though performed seventeen times, was afterwards consigned to oblivion. The fury of the rival parties continued unabated, even after Gluck's departure from Paris in 1780; and an attempt was afterwards made to inaugurate a new rivalry with Sacchini. Still, Piccini held a good position, and on the death of Gluck, in 1787, proposed that a public monument should be erected to his memory,—a suggestion which the Gluckists themselves declined to support. On the breaking out of the Revolution in 1789, Piccini returned to Naples, where he was at first well received by King Ferdinand IV.; but the marriage of his daughter to a French democrat brought him into irretrievable disgrace. For nine years after this he maintained a precarious existence in Venice, Naples, and Rome; but, deriving new hope from the declaration of peace, he returned in 1798 to Paris, where the fickle public received him with enthusiasm, but left him to starve. He died at Passy, May 7, 1800.

Fétis gives a complete list of Piccini's works, including eighty operas, and much choral music. It is certain that the list of operas is very far from complete.

**PICENUM**. See **ITALY**, vol. xiii. pp. 444, 447.

**PICHEGRU, CHARLES** (1761–1804), the conqueror of Holland, was born at Arbois in the Jura on February 16, 1761. His father was only a labourer, but the friars who managed the college of Arbois gave the boy a good education, and one of his masters, the Père Patraut, took him to the military school of Brienne. In 1783 he entered the first regiment of artillery, where he rapidly rose to the rank of adjutant-sub-lieutenant. When the Revolution began he at once became leader of the extreme revolutionary party in Besançon, where he was stationed; and, when a regiment of volunteers of the department of the Gard marched through the city, the popular society recommended him for the rank of lieutenant-colonel, to which he was at once elected. The fine condition of his regiment was soon remarked in the army of the Rhine, to which it was attached, and his organizing ability was made use of by an appointment on the staff, and finally by his promotion to the rank of general of brigade. In 1793, when Dumouriez had deserted, and all generals of noble birth had been superseded, Carnot and Saint Just were sent to find *roturier* generals who could be successful; Carnot discovered Jourdan, and Saint Just discovered Hoche and Pichegru. In co-operation with Hoche and the army of the Moselle, Pichegru, now general of division and in command of the army of the Rhine, had to reconquer Alsace and reorganize the disheartened troops of the republic. They succeeded; Pichegru, instead of fighting great battles, made use of the *élan* of his soldiers to win innumerable small engagements, and with Hoche forced the lines of Haguenau, and relieved Landau. In December 1793 he superseded Hoche, became commander-in-chief of the united armies of the Rhine and Moselle, whence he was summoned to succeed Jourdan in the army of the North in February 1794. It was now that he fought his three great campaigns of one year. The English and Austrians held a strong position along the Sambre to the sea. After vainly attempting to break the Austrian centre, Pichegru suddenly turned their left, and defeated Clerfayt at Cassel, Menin, and Courtrai, while Moreau, his second in command, defeated Coburg at Turcoing in May 1794; then after a pause, during which

Pichegru feigned to besiege Ypres, he again dashed at Clerfayt and defeated him at Rousselaer and Hooglede, while Jourdan came up with the new army of the Sambre and Meuse, and utterly routed the Austrians at Fleurus on June 27, 1794. After a pause Pichegru began his second campaign by crossing the Meuse on October 18, and after taking Nimeguen drove the Austrians beyond the Rhine. Instead of going into winter-quarters, he prepared his army for a winter campaign. On December 28th he crossed the Meuse on the ice, and stormed the island of Bommel, then crossed the Waal in the same manner, and, driving the English before him, entered Utrecht on January 19, and Amsterdam on January 20, and soon occupied the whole of Holland. This grand feat of arms was marked by many points of interest, such as the capture of the Dutch ships which were frozen in the Helder by the French hussars, and the splendid discipline of the ragged battalions in Amsterdam, who, with the richest city of the Continent to sack, yet behaved with perfect self-restraint. This conquest aroused a storm of admiration in France. The former friend of Saint Just now offered his services to the Thermidorians, and after receiving from the Convention the title of Sauveur de la Patrie, subdued the *sans-culottes* of Paris, when they rose in insurrection against the Convention on 12 Germinal (1 April). Honoured by the republicans, and with the greatest military reputation in France, Pichegru then took command of the armies of the North, the Sambre and Meuse, and the Rhine, and crossing the Rhine in force took Mannheim in May 1795. When his fame was thus at its height he became a traitor, and for the promise of a marshal's baton, the governorship of Alsace, the castle of Chambord, 1,000,000 francs in cash, and 200,000 francs a year, sold his army and his country. He allowed Jourdan to be beaten before Mannheim, and betrayed all his plans to the enemy. His intrigues were suspected, and when he offered his resignation to the Directory in October 1795 it was to his surprise promptly accepted. He retired in disgrace, but hoped to serve the royalist cause by securing his election to the Council of Five Hundred in May 1797. He was there the royalist leader, and planned a *coup d'état*, but on the 18th Fructidor he was arrested, and with fourteen others deported to Cayenne in 1797. Escaping, he reached London in 1798, and served in the archduke Charles's staff in the campaign of 1799. He went to Paris in August 1803 with Georges Cadoudal to head a royalist rising against Napoleon; but, betrayed by a friend, he was arrested on February 28, 1804, and on April 6th was found strangled in prison. It has often been asserted, but without a shadow of probability, as he was certain to have been condemned if brought to trial, that he was murdered by the orders of Napoleon.

Pichegru's campaigns of 1794 are marked by traits of an audacious genius which would not have disgraced Napoleon; like him, he perceiving the intrinsic fitness of the French soldiers for strokes of daring rather than for sustained battles. But a more thorough traitor never commanded an army. He flattered in turn Saint Just and the Terrorists, the Thermidorians and the Directors, and seemed altogether unmoved by considerations of loyalty or patriotism.

There is no really good life of Pichegru; perhaps the best is Gassier's *Vie du général Pichegru*, Paris, 1811. For his treason, trial, and death consult Mont-*guyard's Mémoires concernant la trahison de Pichegru*, 1804; Fauche-Borel's *Mémoires, Savary, Mémoires sur la Mort de Pichegru*, Paris, 1825; and G. Pierrat, *Pichegru, son Prises et son Mort*, 1826.

**PICKLES.** The term pickle was originally applied to herrings preserved in salt brine, and by a pickle is still meant any preservative solution for either animal or vegetable food, that for flesh and fish being a brine of common salt, usually with saltpetre, sugar, and certain spices added, while for vegetable substances vinegar is the principal pickling medium. Preparations of the latter description—vegetables saturated with vinegar—constitute the ordinary pickles of domestic use. Acid fruits and succulent fleshy vegetables are the proper materials for pickles.

The vegetable substances principally treated in this way are—beetroot, cabbage, cauliflower, gherkins (small cucumbers), capers, French beans, onions, shallots, mushrooms, green peaches, mangoes, green walnuts, and several tropical fruits besides those mentioned. These are variously dealt with. Such as are soft and in themselves hot and spicy require simply to have vinegar of the proper strength poured over them, after the materials have been carefully selected, washed, and, if necessary, shred. Vegetable substances of a harder and tougher character require first to be steeped in salt brine for some time, then washed, and the vinegar poured over them hot; and yet more leathery and fibrous vegetables must be softened with boiling brine, and then prepared with boiling vinegar. The vinegar employed may be either wood or strong malt vinegar; the former, being free from mucilage, has no tendency to fermentation, and can be obtained of greater strength than that prepared from malt. The vinegar is commonly flavoured with spices or aromatic herbs, flavours being chosen with special reference to the fruit or vegetable operated on. The flavouring materials, of which pepper, allspice, red pepper, cloves, horse-radish, garlic, and ginger are examples, are either added whole to the pickle or may be separately infused in the vinegar. For the preservation of pickles it is necessary that the jars in which they are stored should be secured with stoppers tied over with bladder and sealed, so as to render them as far as possible air-tight. It is of the utmost consequence that in the compounding and storing of these acid preparations no vessels or fittings of copper, brass, zinc, or lead, which yield, with acetic acid, poisonous products, should be used. Contamination with copper is especially to be avoided; yet, as small quantities of acetate of copper give to pickled vegetables a fine, fresh green, natural colour, such an adulteration is not unfrequently practised; and some of the older cookery books actually recommend the use of copper vessels, and even the addition of small pieces of verdigris, to improve the colour of the pickles. As food adjuncts, pickles should be sparingly used, their chief merit being piquancy, though the acid they contain exercises a solvent influence on the more directly nutritious constituents of food, and the added spices having a stimulating effect, they thus aid the process of digestion.

**PICO, GIOVANNI, OF MIRANDOLA** (1463–1494), was the youngest son of Giovanni Francesco Pico, prince of Mirandola, a small territory about 30 Italian miles west of Ferrara, afterwards absorbed in the duchy of Modena. The family was illustrious and wealthy, and claimed descent from Constantine. From his childhood Pico was remarkable for his quick and tenacious memory, and gave promise of his future distinction as a scholar. In his fourteenth year he went to Bologna, where he studied for two years, and was much occupied with the Decretals. The traditional studies of the place, however, disgusted him; he was eager to know all the secrets of nature, and devoting himself wholly to speculative learning he spent seven years wandering through all the schools of Italy and France and collecting a precious library. Like most men with brilliant faculties of acquisition and assimilation, Pico was constitutionally an eclectic; and he owes his place in the history of inquiry which left him dissatisfied with current teaching and drove him to studies then new and strange. Besides Greek and Latin he knew Hebrew, Chaldee, and Arabic; and his Hebrew teachers (Elijah del Medigo, Leo Abarbanel, and Jochanan Aleman—see L. Geiger, *Johann Reuchlin* [1871], p. 167) introduced him to the Kabbalah, which had great fascinations for one who loved all mystic and theosophic speculation. His learned wanderings ended at Rome, where he set forth for public disputation a list of nine hundred questions and conclusions in all branches of

philosophy and theology. He remained a year in Rome, but the disputation he proposed was never held. He was an object of envy to many for the range of attainments, which earned him the title of the Phoenix of his age, and detractors found it easy to fix on his conclusions a suspicion of heresy. The pope prohibited the little book in which they were contained, and Pico had to defend the impugned theses in an elaborate *Apologia*. His personal orthodoxy was, however, finally vindicated by a brief of Alexander VI., dated 18th June 1493. The suspected theses included such points as the following:—that Christ descended *ad inferos* not in his real presence but *quoad effectum*; that no image or cross should receive *latreia* even in the sense allowed by Thomas; that it is more reasonable to regard Origen as saved than as damned; that it is not in a man's free will to believe or disbelieve an article of faith as he pleases. But perhaps the most startling thesis was that no science gives surer conviction of the divinity of Christ than "magic" (*i.e.*, the knowledge of the secrets of the heavenly bodies) and Kabbalah. Pico was the first to seek in the Kabbalah a proof of the Christian mysteries, and it was by him that Reuchlin was led into the same delusive path.

Pico had been up to this time a gay Italian nobleman; he was tall, handsome, fair-complexioned, with keen grey eyes and yellow hair, and a great favourite with women. But his troubles led him to more serious thoughts; he burned his amorous verses and gave himself wholly to sacred letters, publishing as the first fruits of his studies, in his twenty-eighth year, the *Heptaplus*, a mystical exposition of the creation. Next he planned a great sevenfold work against the enemies of the church, of which only the section directed against astrology was completed. After leaving Rome he again lived a wandering life, often visiting Florence, to which he was drawn by his friends Politian and Marullus Ficinus, and where also he came under the influence of Savonarola. It was at Florence that he died in 1494. Three years before his death he parted with his share of the ancestral principality, and gave much of his wealth to the poor. He was now increasingly absorbed in ascetic exercises and religious meditation, and designed, when certain literary plans were completed, to give away all he had and wander barefoot through the world preaching Christ, or perhaps to join the preaching friars. But these plans were cut short by a fever which carried him off just at the time when Charles VIII. was at Florence. Pico's attainments and the beauty of his character and piety produced a profound impression on his contemporaries, but his works, published by his nephew Giov. Fran. Pico, with a biography, at Bologna in 1496, and more than once reprinted, cannot now be read with much interest. The man himself, however, is still interesting, partly from his influence on Reuchlin and partly from the spectacle of a truly devout mind in the brilliant circle of half-pagan scholars of the Florentine renaissance.

PICTON, SIR THOMAS (1758-1815), general under Wellington in the Peninsular War, was the younger son of Thomas Picton, of Poyston, Pembrokeshire, where he was born in August 1758. In 1771 he obtained an ensign's commission in the 12th regiment of foot, but he did not join until two years afterwards. The regiment was then stationed at Gibraltar, where he remained until he was made captain in the 75th in January 1778, when he returned to England. The regiment was shortly afterwards disbanded, and in 1794 he embarked for the West Indies without an appointment, on the strength of a slight acquaintance with Sir John Vaughan, who made him his aide-de-camp and gave him a captaincy in the 17th foot. Shortly afterwards he was promoted major. Under Sir Ralph Abercromby he took part in the capture of St Lucia

and St Vincent. After the reduction of Trinidad he was made governor of the island, and in October 1801 he was gazetted brigadier-general. Resigning the governorship of Trinidad in 1803, he took part in an expedition against St Lucia and Tobago, and he held the governorship of the latter island until forced to resign it by public clamour in England. In 1807 he was put upon his trial for applying torture to a female slave in Trinidad to extort confession respecting a robbery, and a general verdict of guilty was returned. A new trial was, however, granted, and after protracted litigation the court, on 10th February 1810, ordered "the defendant's recognizance to be respited until they should further order." Previous to this he had taken part in the capture of Flushing, of which in 1809 he was made governor. At the special solicitation of Wellington he was named to the command of a division of the army in Spain, and during the Peninsular campaign he was placed in the post of honour, and so distinguished himself that he seven times received the thanks of the House of Commons. The capture of Badajoz was effected chiefly through his daring self-reliance and penetration in converting what was intended to be only a feint attack into a real one. At the battle of Quatre Bras on the 16th June 1815 he was dangerously wounded, and at Waterloo on the 18th, while repulsing with impetuous valour what Wellington denominated "one of the most serious attacks made by the enemy on our position," he was struck dead by a ball on the temple. A public monument was erected to his memory in St Paul's Cathedral.

PIEDMONT (Italian, *Piemonte*; Low Latin, *Pedemoni* and *Pedemontium*), a region of northern Italy, bounded N. by Switzerland, W. by France, S. by Liguria, and E. by Lombardy. Physically it may be briefly described as the upper gathering-ground and valley of the river Po, enclosed on all sides except towards the Lombard plain by the vast semicircle of the Pennine, Graian, Cottian, Maritime, and Ligurian Alps. In 1859 it was divided into the four provinces of Alessandria, Cuneo, Novara, and Torino (Turin), which still remain as provinces of the kingdom of Italy. In 1858 its population was 2,738,814.

The name of Lombardy was used as inclusive of the upper valley of the Po as late as 1091, when the house of Savoy lost most of its Italian possessions by the death of Adelaide; but in the time of Thomas I. (1177-1233), duke of Savoy, while the name Savoy was applied more especially to the ducal territory on the French side of the Alps, that of Piedmont came into use as a collective term for the territory on the Italian side. Thomas II. of Savoy, count (not Thomas III., count of Savoy, as he is often wrongly called), son of Thomas I., obtained (1255) part of Piedmont as an appanage from his brother Amadeus IV., and was appointed imperial vicar in Piedmont by Frederick II.; and, though he was afterwards obliged to renounce all the concessions he had received alike from pope and emperor, his son Thomas III. became the founder of the line which bore the title "Princes of Achaia and Morea, and lords of Piedmont." Louis, the last of these lords, dying in 1418, left his possessions to Amadeus VIII.

PIERCE, FRANKLIN (1804-1869), fourteenth president of the United States, was descended from an old yeoman family of New England, and was born at Hillsborough, New Hampshire, 23d November 1804. His father, Benjamin Pierce, served through the revolutionary war, afterwards attaining the rank of major-general, and became governor of his State. The son entered Bowdoin College, Brunswick, Maine, in 1820. Nathaniel Hawthorne, who was in the class below him, and was his intimate friend, mentions as his most notable characteristic at this time his "fascination of manner, which has proved so magical in winning him an unbounded popularity." The same characteristic remained with him through life, and was the chief

cause of his success. His abilities did not greatly impress his classmates, and, although he took at length a good position, he was not distinguished for scholarship. After leaving college in 1824 he studied law with Judge Woodbury at Portsmouth, and afterwards in the law school at Northampton, Mass., and with Judge Parker at Amherst, and came to the bar in 1827. His first appearance as a pleader was a failure, but this only incited him to redoubled perseverance and determination. From the first he was a zealous supporter of the Democratic party, and he took an active part in promoting the election of Andrew Jackson to the presidency. In 1829 he was elected by his native town to the State legislature, of which he was speaker in 1832-33. In the latter year he was chosen a member of Congress, and in 1837 he was elected to the senate of the United States. He displayed no striking oratorical gifts, but as a member of the judiciary and other committees gained general respect. In 1842 he resigned his seat in the senate, and returned to the practice of the law. His reputation at the bar was very high, his success being largely due to his power of identifying himself with his client's cause, and his strong personal influence over a jury. In 1846 he was offered the position of attorney-general of the United States, but declined it. On the outbreak of the Mexican War he joined as a volunteer one of the companies raised in Concord. He was soon after appointed colonel of the 9th regiment, and in March 1847 brigadier-general. At the battle of Contreras on the 19th of August he was severely injured by the fall of his horse. At the close of the war in December 1847 he resigned his commission. In 1850 he was president of the convention for revising the constitution of New Hampshire. In 1852, as candidate of the Democratic party, he was elected president of the United States by 254 electoral votes against 42 given to General Scott. The special feature of his inaugural address was the support of slavery in the United States, and the announcement of his determination that the Fugitive Slave Act should be strictly enforced. This was the keynote of his administration, and pregnant with vital consequences to the country. From it came during his term the Ostend conference and "manifesto," the repeal of the Missouri compromise, and the troubles in Kansas and Nebraska, which crystallized the opposing forces into the Republican party, and led later to the great rebellion. President Pierce, surrounded by an able cabinet, among them Jefferson Davis as Secretary of War, firmly adhered throughout his administration to the pro-slavery party. He failed, notwithstanding, to obtain re-nomination, but was succeeded by James Buchanan, March 4, 1857, and retired to his home in Concord, N. H., after spending some years in Europe. During the war of 1861-65 his sympathies were wholly with the South, but, with the exception of delivering a strong speech at Concord in 1863, he took no very active part in politics. He died 8th October 1869.

Among several lives of General Pierce, published during his candidature for the presidency, special mention may be made of that by his friend Nathaniel Hawthorne.

**PIERO (or PIETRO) DE' FRANCESCHI** (1415-1492), a leading painter of the Umbrian school. This master is generally named *Piero della Francesca* (Peter, son of Frances), the tradition being that his father, a woollen-draper named Benedetto, had died before his birth. This is not correct, for the mother's name was Romana, and the father continued living during many years of Piero's career. The painter is also named *Piero Borghese*, from his birthplace, Borgo San Sepolcro, in Umbria. The true family name was, as above stated, *Franceschi*, and the family still exists under the name of *Martini-Franceschi*.

Piero first received a scientific education, and became an adept in mathematics and geometry. This early bent

of mind and course of study influenced to a large extent his development as a painter. He had more science than either Paolo Uccello or Mantegna, both of them his contemporaries, the former older and the latter younger. Skilful in linear perspective, he fixed rectangular planes in perfect order and measured them, and thus got his figures in true proportional height. He preceded and excelled Domenico Ghirlandajo in projecting shadows, and rendered with considerable truth atmosphere, the harmony of colours, and the relief of objects. He was naturally therefore excellent in architectural painting, and, in point of technique, he advanced the practice of oil-colouring in Italy.

The earliest trace that we find of Piero as a painter is in 1439, when he was an apprentice of Domenico Veneziano, and assisted him in painting the chapel of S. Egidio, in S. Maria Novella of Florence. Towards 1450 he is said to have been with the same artist in Loreto; nothing of his, however, can now be identified in that locality. In 1451 he was by himself, painting in Rimini, where a fresco still remains. Prior to this he had executed some extensive frescos in the Vatican; but these were destroyed when Raphael undertook on the same walls the Liberation of St Peter and other paintings. His most extensive extant series of frescos is in the choir of S. Francesco in Arezzo,—the History of the Cross, beginning with legendary subjects of the death and burial of Adam, and going on to the entry of Heraclius into Jerusalem after the overthrow of Chosroes. This series is, in relation to its period, remarkable for effect, movement, and mastery of the nude. The subject of the Vision of Constantine is particularly vigorous in chiaroscuro; and a preparatory design of the same composition was so highly effective that it used to be ascribed to Giorgione, and might even (according to one authority) have passed for the handiwork of Correggio or of Rembrandt. A noted fresco in Borgo San Sepolcro, the Resurrection, may be later than this series; it is preserved in the Palazzo de' Conservatori. An important painting of the Flagellation of Christ, in the cathedral of Urbino, is later still, probably towards 1470. Piero appears to have been much in his native town of Borgo San Sepolcro from about 1445, and more especially after 1454, when he finished the series in Arezzo. He grew rich there, and there he died, and in October 1492 was buried.

Two statements made by Vasari regarding "*Piero della Francesca*" are open to much controversy. He says that Piero became blind at the age of sixty, which cannot be true, as he continued painting some years later; but scepticism need perhaps hardly go to the extent of inferring that he was never blind at all. Vasari also says that Fra Luca Pacioli, a disciple of Piero in scientific matters, defrauded his memory by appropriating his researches without acknowledgment. This is hard upon the friar, who constantly shows a great reverence for his master in the sciences. One of Pacioli's books was published in 1509, and speaks of Piero as still living. Hence it has been propounded that Piero lived to the patriarchal age of ninety-four or upwards; but, as it is now stated that he was buried in 1492, we must infer that there is some mistake in relation to Pacioli's remark—perhaps the date of writing was several years earlier than that of publication. Piero was known to have left a manuscript of his own on perspective; this remained undiscovered till a recent date, when it was found by E. Harzen in the Ambrosian Library of Milan, ascribed to some supposititious "*Pietro, Pittore di Bruges*." The treatise shows a knowledge of perspective as dependent on the point of distance.

In the London National Gallery are four paintings attributed to Piero de' Franceschi. One of them, a profile of Isotta da Rimini, may safely be rejected. The Baptism of Christ, which used to be the altarpiece of the Priory of the Baptist in Borgo San Sepolcro, is an important example; and still more so the Nativity, with the Virgin kneeling, and five angels singing to musical instruments. This is a very interesting and characteristic specimen, and has indeed been praised somewhat beyond its deservings on æsthetic grounds.

Piero's earlier style was energetic but unrefined, and to the last he lacked selectness of form and feature. The types of his visages are peculiar, and the costumes (as especially in the Arezzo series)

singular. He used to work assiduously from clay models swathed in real drapery. Luca Signorelli was his pupil, and probably to some extent Perugino; and his own influence, furthered by that of Signorelli, was potent over all Italy. Belonging as he does to the Umbrian school, he united with that style something of the Siennese and more of the Florentine mode.

**PIETISM.** Pietism is the name of an exceedingly influential, instructive, and interesting movement in the Lutheran Church which arose towards the end of the 17th and continued during the first half of the following century. The name of Pietists was given to the adherents of the movement by its enemies, as a term of ridicule, like that of "Methodists" somewhat later in England. The origin and nature of the movement itself may be both traced to defects in the Lutheran Church of the time and to isolated efforts to correct them. That church had in the 17th century become a creed-bound theological and sacramentarian institution, which orthodox theologians ruled with almost the absolutism of the papacy. Correctness of creed had taken the place of deep religious feeling and purity of life. Christian faith had been dismissed from its seat in the heart, where Luther had placed it, to the cold regions of the intellect. The dogmatic formularies of the Lutheran Church had usurped the position which Luther himself had assigned to the Bible alone, and as a consequence they only were studied and preached, while the Bible was neglected in the family, the study, the pulpit, and the university. Instead of advocating the priesthood of all believers, so powerfully proclaimed by Luther, the Lutheran pastors had made themselves a despotic hierarchy, while they neglected the practical pastoral work of caring for the moral and spiritual welfare of their flocks. One of the consequences, as the Pietists believed, of all this was that immorality, irreligion, and heathenish ignorance of Christianity abounded in the land, and cried to heaven against an unfaithful church. A forerunners of the Pietists in the strict sense, not a few earnest and powerful voices had been heard bemoaning the shortcomings of the church and advocating a revival of practical and devout Christianity. Amongst them were Jacob Boehme (Bremen), the theosophic mystic; Johann Arndt, whose principal devotional work on *True Christianity* is universally known and appreciated; Heinrich Muller, who described the font, the pulpit, the confessional, and the altar as the four dumb idols of the Lutheran Church; the theologian Johann Valentin Andrea, the court chaplain of the Landgrave of Hesse; Schuppilus, who sought to restore to the Bible its place in the pulpit; and Theophilus Grossgebauer of Rostock, who from his pulpit and by his writings raised "the alarm cry of a watchman in Zion." The direct originator of the movement was Philip Jacob Spener. Born in Alsace January 13, 1635, as a child trained in piety under the influence of a devout godmother and books of devotion recommended by her, particularly Arndt's *True Christianity*, accustomed to hear the sermons of a pastor who preached the Bible more than the Lutheran creeds, he was early convinced of the necessity of a moral and religious reformation of the German church. He studied theology, with a view to the Christian ministry, at Strasburg, where the professors at the time were more inclined to practical Christianity than to theological disputation. He afterwards spent a year in Geneva, and was powerfully influenced by the strict moral life and rigid ecclesiastical discipline prevalent there, and also by the preaching and the piety of the Waldensian professor Antoine Leger and the converted Jesuit preacher Jean de Labadie. During a stay in Tübingen he read Grossgebauer's *Alarm Cry*, and in 1666 he entered upon his first pastoral charge at Frankfort-on-the-Main, profoundly impressed with a sense of the danger of the Christian life being sacrificed to zeal for rigid orthodoxy. Pietism, as a

distinct movement in the German church, was then originated by Spener by religious meetings at his house (*collegia pietatis*), at which he repeated his sermons, expounded passages of the New Testament, and induced those present to join in conversation on religious questions that arose. These meetings were largely attended, produced a great sensation, and were soon imitated elsewhere. They gave rise to the name "Pietists." In 1675 Spener published his *Pia Desideria*, or *Earnest Desires for a Reform of the True Evangelical Church*, the public literary exposition and defence of his position and aims. In this publication Spener made six proposals as the best means of restoring the life of the church:—(1) the earnest cultivation of a more general and thorough familiarity with the Holy Scriptures by means of private meetings, *ecclesiæ in ecclesiâ*; (2) a practical carrying out of the principle of the universality of the Christian priesthood by a participation of the laity in the spiritual government of the church and by the holding of family worship; (3) a serious laying to heart of the fact that a knowledge of Christianity must be attended by the practice of it as its indispensable sign and supplement; (4) the conversion of the habit of making merely didactic, and often bitter, attacks on the heterodox and unbelievers into a treatment of them instigated by genuine affection and animated by the simple desire of doing them good; (5) a reorganization of the theological training of the universities, in such a way that young divines should be urged not only to diligence in their studies but above all to lead devout lives; and (6) a different style of preaching, namely, in the place of pleasing rhetoric, the implanting of Christianity in the inner or new man, the soul of which is faith, and its effects the fruits of life. This work produced a great impression throughout Germany. Although large numbers of the orthodox Lutheran theologians and pastors were deeply offended by it, its complaint and its demands were both too well justified to admit of their being point-blank denied. A large number of pastors at once practically adopted Spener's proposals. In 1686 Spener accepted an appointment to the court-chaplaincy at Dresden, which opened to him a wider though more difficult sphere of labour. He succeeded in reviving the catechetical instruction of the young in religious truth in Saxony. In Leipsic, where Scriptural exegesis had almost wholly disappeared, a society of young theologians was formed under his influence, for the learned study and devout application of the Bible. Three *magistri* belonging to that society, one of whom was August Hermann Francke, subsequently the founder of one of the noblest works of Pietism—the orphanage at Halle—commenced courses of expository lectures on the Scriptures of a practical and devotional character and in the German language, which were zealously frequented by both students and townsmen. The lectures aroused, however, the ill-will of the other theologians and pastors of Leipsic, and their promoters, charged with having slighted the established worship of the land as well as true learning, were ordered to discontinue them. Francke and his friends left the city, and with the aid of Christian Thomasius and Spener founded the new university of Halle, which became the chief home of the Pietists, and the object of the jealousy and unsparing attacks of the older universities of Wittenberg and Leipsic. The theological chairs in the new university were filled in complete conformity with Spener's proposals. The main difference between the new Pietistic school and the orthodox Lutherans was not one affecting doctrine directly, inasmuch as Spener adhered in every point to the Lutheran faith. The difference arose from his conception of Christianity as chiefly consisting in a change of heart and consequent holiness of life, while the orthodox Lutherans

of North America, *Ectopistes migratorius*, which is still plentiful in many parts of Canada and the United States, though no longer appearing in the countless numbers that it did of old, when a flock seen by Wilson was estimated to consist of more than 2230 millions. The often-quoted descriptions given by him and Audubon of Pigeon-haunts in the then "back woods" of Kentucky, Ohio, and Indiana need not here be reproduced. That of the latter was declared by Waterton to be a gross exaggeration if not an entire fabrication; but the critic would certainly have changed his tone had he known that, some hundred and fifty years earlier, Passenger-Pigeons so swarmed and ravaged the colonists' crops near Montreal that a bishop of his own church was constrained to exorcise them with holy water, as if they had been demons.<sup>1</sup> The rapid and sustained flight of these Pigeons is also as well-established as their former overwhelming abundance—birds having been killed in the State of New York whose crops contained undigested grains of rice that must have been not long before plucked and swallowed in South Carolina or Georgia. The Passenger-Pigeon is about the size of a common Turtle-Dove, but with a long, wedge-shaped tail. The male is of a dark slate-colour above, and purplish-bay beneath, the sides of the neck being enlivened by gleaming violet, green, and gold. The female is drab-coloured above and dull white beneath, with only a slight trace of the brilliant neck-markings.<sup>2</sup>

Among the multitudinous forms of Pigeons very few can here be noticed. A species which seems worthy of attention as being one that might possibly repay the trouble of domestication, if any enterprising person would give it the chance, is the Wonga-wonga or White-fleshed Pigeon of Australia, *Lewinsia picta*, a bird larger than the Ring-Dove, of a slaty-blue colour above and white beneath, streaked on the flanks with black. It is known to breed, though not very freely, in captivity, and is said to be excellent for the table. As regards flavour, however, those who have been so fortunate as to eat them declare that the Fruit-Pigeons of the genus *Treron* (or *Vinago* of some authors) and its allies surpass all birds. These inhabit tropical Africa, India, and especially the Malay Archipelago; but the probability of domesticating any of them is very remote. Hardly less esteemed are the Pigeons of the genus *Ptilopus* and its kindred forms, which have their headquarters in the Pacific Islands, though some occur far to the westward, and also in Australia. Among them are found the most exquisitely-coloured of the whole Family. There may be mentioned the strange Nicobar Pigeon, *Calenas*, an inhabitant of the Indian Archipelago, not less remarkable for the long lustrous hackles with which its neck is clothed than for the structure of its gizzard, which has been described by Prof. Flower (*Proc. Zool. Society*, 1860, p. 330), though this peculiarity is matched or even surpassed by that of the same organ in the *Phenorrhina goliath* of New Caledonia (*Rec. de Zoologie*, 1862, p. 138) and in the *Carpophaga latrans* of Fiji. In this last the surface of the epithelial lining is beset by horny conical processes, adapted, it is believed, for crushing the very hard fruits of *Oncocarpus vitiensis* on which the bird feeds (*Proc. Zool. Society*, 1878, p. 102). The modern giants of the group, consisting of about half a dozen species of the genus *Goura* and known as

Crowned-Pigeons, belong to New Guinea and the neighbouring islands, but want of space forbids further notice of their characteristics, of which the most conspicuous are their large size and the reticulated instead of scutellated covering of their "tarsi."

A very distinct type of Pigeon is that represented by *Didunculus strigirostris*, the "Manu-mea" of Samoa, still believed by some to be the next of kin to the Dove (vol. vii. p. 321), but really presenting only a superficial resemblance in the shape of its bill to that effete form, from which it differs osteologically quite as much as do other Pigeons (*Phil. Transactions*, 1869, p. 349). It remains to be seen whether the Papuan genus *Otidiphaps*, of which several species are now known, may not belong rather to the *Didunculidæ* than to the true *Columbidæ* (see ORNITHOLOGY, vol. xviii. p. 46).

At least 500 species of Pigeons have been described, and many methods of arranging them suggested. That by Garrod (*Proc. Zool. Society*, 1874, pp. 249–259) is one of the most recent; but, for reasons before assigned (vol. xviii. p. 40), it is not satisfactory. Temminck's great work on the group with its continuation by M. Florent-Provost, already mentioned (vol. xviii. p. 11), is of course wholly out of date, as also Selby's more modest *Natural History of the Columbidae* (forming vol. ix. of Jardine's *Naturalist's Library*). Schlegel's catalogue of the specimens contained in the museum at Leyden (*Museum des Pays-Bas*, livr. 10, 1873) contains much useful information, but a new monograph of the Pigeons, containing all the recent discoveries, is much wanted. (A. S.)

PIGMENTS are coloured powders which, when mixed with oil, water, or other fluids, in which they are insoluble, form paints. They are distinguished from dyes and washes by their entire insolubility in the media in which they are mixed, whereas dye-stuffs are tinctorial substances applied in solution. Insoluble colours, when used in printing textile fabrics, are distinguished as pigment colours. The sources of materials available as pigments are numerous; many are native coloured earths, others are separated from native metallic compounds and other mineral substances; a large number are artificially prepared from inorganic—principally metallic—sources; an important class consist of animal and vegetable colouring principles, forming with earthy bodies insoluble powders called lakes; and the dye-stuffs artificially obtained from organic sources are also similarly utilized. In fact all substances coloured or neutral, capable of being presented in the form of impalpable powder, which at the same time are insoluble and unalterable under ordinary atmospheric influences, may be regarded as possible pigments. But there are many qualities practically essential in a pigment which limit the range of available substances. A consideration of the first importance is the "body" or covering power of a pigment,—that is, the property of fully covering and concealing with an opaque coating the surface over which it is spread. It is also important that the material should work well in, and be unaffected in appearance and constitution by the medium with which it is made into a paint, and that it should spread in an even uniform coat, which should dry well and quickly in the air and adhere firmly to the surface to which it is applied. When dry it should possess durability and resist change under the action of weather and other influences to which paint is exposed. These are the principal qualities requisite in paints in their important function of preservative coatings for the surfaces to which they are applied. On their artistic side, as decorative and pictorial materials, pigments should possess purity and brightness of colour with intensity of tinting power, capacity for mixing or coming into contact with other colours without injuriously

<sup>1</sup> *Voyages du Baron de la Hontan dans l'Amerique septentrionale*, ed. 2, Amsterdam, 1705, vol. i. pp. 93, 94. In the first edition, published at The Hague in 1703, the passage, less explicit in details but to the same effect, is at p. 86. The author's letter, describing the circumstance, is dated May 1657.

<sup>2</sup> There are several records of the occurrence in Britain of this Pigeon, but in most cases the birds noticed cannot be supposed to have found their own way hither. One, which was shot in Fife in 1525, may, however, have crossed the Atlantic unassisted by man.

affecting these or being themselves deteriorated, and permanence and unalterability of tone after long exposure.

Pigments being so numerous and so diverse in their origin, the industries connected with their production and preparation are of necessity varied in character. Many of the substances employed being used in large quantities in other important industrial relations, as well as for paints, are manufactured on a large scale and constitute the basis of considerable chemical industries, as, for example, the manufacture of white lead, Prussian blue, ultramarine, the chrome materials, &c. In other cases the materials require no preparation other than that given to them by the paint-grinder or the artists' colourman, according to the purpose for which the substances are to be prepared.

The colour trade embraces two distinct departments:—that of the paint-grinder, who manufactures and compounds the pigments used by artisans, house-painters, and paper-stainers; and that of the artists' colourman, who prepares and supplies the finer, more brilliant, and extensive assortment of pigments used for artistic purposes. The pigments employed for pottery painting and glass and enamel work are a special class of preparations to suit the requirements of these trades. Leaving out of account the chemical reactions involved in preparing raw materials, the ordinary manufacturing operations connected with the preparation of painters' colours are simple, and consist essentially of a careful system of grinding. Formerly, when painters ground their own colours, a stone slab and muller formed the entire apparatus; but now, when paint-grinding has become a separate industry, efficient machinery has been devised for grinding and its collateral operations. Bulky and rough colours such as whiting and common ochres are dry-ground under heavy edge stones which revolve in a strong iron bed. Ordinary dry colours requiring to be pulverized with more care are mixed to a thin cream with water, which is fed into and ground principally between a pair of millstones dressed and mounted like the ordinary horizontal stones of a flour mill, but smaller in diameter. For fine colours the pigment so ground is levigated, or floated into a vat in which the heavier particles sink, and the lighter, more finely divided portion is run into another vessel at a lower level, where it is deposited as a fine sediment. The sediment is dried in a uniformly heated stove, and when thoroughly dry is again pulverized under a pair of edge stones, and sifted or winnowed; so treated it is ready for use as dry colour. The greater proportion of the white lead and the other common oil paints are ground in oil. For this purpose the raw material is mixed in a machine with oil (sometimes boiled) to the consistence of a stiffish paste, and in this state it is ground in horizontal paint millstones, after which it requires no further preparation than the necessary thinning with oil when to be used for painting. There are many varieties of apparatus used for grinding both dry and oil colours.

The artists' colourman grinds his pigments with much greater labour, and selects his materials in a more careful manner, than is necessary in the case of the ordinary paint-grinder. Pigments for artistic painting in oil are ground in that medium to a definite consistency, and are put up for use in convenient compressible tubes of tin. For water colours the pigments are prepared principally in the form of small indurated cakes or as "moist colours" contained in small porcelain dishes. Water colours may also be obtained thin in tin tubes like oil colours, or as "pastilles," which are thin round cakes intermediate in condition between cake and moist colours.

In enumerating the principal commercial pigments it is usual and convenient to classify them according to their tints. They are not, as a rule, definite chemical com-

pounds: many indeed are mixed substances prepared by processes and according to recipes known only to their makers; and, while the same commercial name is frequently given to substances quite dissimilar in character, the confusion is further increased by applying many different titles to substances which are practically identical. Thus white lead is known by at least a dozen names, and distinct and even conflicting qualities are by authorities attributed to this one substance under its various aliases.

It would be impossible to catalogue all the paints met with in commercial lists, and it would serve no good purpose to enumerate the whole of the pigments which might be and are occasionally used. Premising that details regarding many of the substances will be found under the heading of the metals, &c., whence they are derived, we shall here simply classify, according to their colour, the principal well-recognized pigments of commerce, adding brief remarks regarding each class.

**WHITE PIGMENTS.**—The whites are the most important pigments used by painters, forming as they do the basis or body of nearly all paints, excepting only certain dark hues. Good available whites are limited in number, and all of real importance are included in the following list:—white lead, a carbonate of lead (chiefly); zinc white, oxide of zinc, called also Chinese white; antimony white, oxide of antimony; fixed white, sulphate of baryta; "silicate" white, sulphate of baryta, or strontia and sulphide of zinc; mineral white, powdered gypsum (with alumina it forms satin white); chalk or whiting carbonate of lime; and china clay, silicate of alumina.

**White Lead** (see LEAD, vol. xiv. p. 378) is the most important of all pigments, and forms the basis of nearly all ordinary oil paints, which, when coloured, consist of white lead tinted with the necessary coloured pigments. It possesses the greatest amount of body or covering power, and works beautifully in oil, with which it partially combines, drying as a hard homogeneous adherent plaster. On the other hand it is a most poisonous body, very injurious to the persons connected with many of the processes by which it is prepared. As an oil colour it darkens gradually in an atmosphere containing traces of sulphur; it cannot be used at all as a water or distemper colour; and it acts injuriously on the colour of several important pigments. Notwithstanding these drawbacks no white has yet been made that can compete with white lead, although paint manufacturers go far to provide a substitute by adulterating it to such an extent that the white lead frequently bears only a small ratio to the adulterant. Baryta white is the ordinary adulterant, and among respectable manufacturers the intermixture is a well-understood fact, and the relative proportions of white lead and baryta are regulated by a series of grades passing from "genuine" to No. 5 or No. 6 white lead. Many efforts have been made to substitute for ordinary white lead lead carbonates made by other processes, and other lead salts such as the oxychloride (Pattinson's), sulphate, tungstate, antimoniate, &c.; but none of these has proved permanently successful.

**Zinc White.**—Next in importance to white lead, is an oxide of zinc prepared by the sublimation and combustion of metallic zinc. The pigment is deficient in covering power and it dries but slowly when mixed with oil. On the other hand it is not injurious to health, its purity of tone is not affected by sulphurous air, it does not affect tints added to it or with which it comes in contact, and it can be used in water as well as in oil. Like white lead it is very much adulterated, and generally with the same agent—baryta white.

**Baryta White** plays an important independent part as well as acting so extensively as a sophisticator of other pigments. It is prepared by grinding to a fine powder the pure white native sulphate of baryta (heavy spar), and the same substance artificially prepared is known as permanent white or *blanc fixe*. The artificial preparation is much superior, as a pigment, to the powdered spar; but both are deficient in body, notwithstanding which they are of great value to paper-stainers and for distemper painting.

Under the name of *Charlton White* or silicate paints, Mr J. B. Orr prepares a range of white paints which have come into extensive use. The pigment as originally prepared under Mr Orr's patent of 1874 consisted of an intimate mixture of artificial sulphate of baryta and sulphide of zinc in certain proportions, made by the double decomposition of solutions of barium sulphide and sulphate of zinc. In 1881 a patent was secured by Mr Orr for a combination in which strontia takes the place of baryta. It is claimed for these pigments that they possess body greater than white lead, that they are non-poisonous, and that with certain modifications in the manufacture they can be made quite as valuable for distemper painting as for oil colours.

The oxides of antimony, tin, bismuth, &c., form white pigments; but these possess no peculiarities which render them valuable for painters' use. The carbonate of lime, more or less pure and in various degrees of pulverulence under several names, such as *Chalk White*, *Paris White*, *Whiting*, &c., is very extensively used in distemper work for walls, roofs, &c., and in paper-staining, occupying in these relations the important place held by white lead in oil painting. Mineral white or satin white consists of powdered gypsum and alumina, a preparation very largely used by paper-stainers for their glossy satin bodies. There are several other white earths of relatively little importance as pigments.

**BLUE PIGMENTS.**—The list of blue colours of real importance is not extensive, comprising, as principal items, ultramarine, Prussian blue, the cobalt blues, and indigo. The following list embraces the names and varieties ordinarily recognized in commerce:—ultramarine (native), powdered lapis lazuli; ultramarine (artificial), silicates of alumina and soda with sulphide of sodium; Prussian blue, cyanide of iron; Paris blue, modified Prussian blue; Antwerp blue, fine Prussian blue; smalts, a cobalt glass; azure blue, a preparation of smalts; cobalt or Thenard's blue, sub-phosphate of cobalt; ceruleum, stannate of cobalt and sulphate of lime; mountain blue, native carbonate of copper; lime blue, carbonate of copper and lime; Verditer or Bremen blue, hydrated oxide of copper; indigo from species of *Indigofera*; indigo carmine, preparation of indigo.

Apart from the important colours **ULTRAMARINE**, **PRUSSIAN BLUE**, and **INDIGO**, separately noticed, these blues, which are not of much value for painters, owe their colour principally to cobalt and copper. The principal cobalt colour is *Smalts*, called also strewing smalts, cobalt glass, zaffre, Saxony blue, &c. It is prepared by smelting together the mineral arsenide of cobalt, pure sand, and carbonate of potash into a glass. The molten glass is cast into cold water, then ground fine and levigated. Smalts is chiefly available for distemper and fresco painting, and is not much used as an oil colour. *Azure Blue* is generally recognized as a preparation of smalts, but the name is given to several compounds. *Ceruleum* is a light blue colour of durable quality with a greenish tinge, consisting of a combination of cobalt oxide with stannic acid; and *Cobalt Blue*, the subphosphate of cobalt, a colour discovered by Thenard, possesses a purple tinge. Carbonate of copper, either in the form of the mineral azurite or artificially prepared, is a principal source of the copper blues, which, however, possess little value as pigments owing to their tendency to blacken under exposure. *Blue Verditer*, a greenish blue which passes into green verditer, is a hydrated oxide of copper.

**YELLOW PIGMENTS.**—The following list includes the ordinary yellow colours of commerce:—ochres and sienna earth, native earths tinted with iron; Mars yellow, hydrated ferric oxide; chromes, chromates of lead and other metals; massicot, protoxide of lead; Naples yellow, antimoniate of lead; mineral yellow, basic chloride of lead; aureolin, nitrate of potassium and cobalt; cadmium yellow, sulphide of cadmium; orpiment, trisulphide of arsenic; Indian yellow, urio-phosphate of calcium; gamboge, resin of *Garcinia*; Dutch pink, a vegetable lake; yellow lakes.

Of these colours the more important are the ochres and the various combinations containing chromium. The *Yellow Ochres* are native earths coloured with hydrated ferric oxide, the brownish yellow substance that colours, and is deposited from, highly ferruginous water. These ochres are of two kinds—one having an argillaceous basis, while the other is a calcareous earth, the argillaceous variety being in general the richer and more pure in colour of the two. Both kinds are widely distributed, fine qualities being found in Oxfordshire, the Isle of Wight, near Jena and Nuremberg in Germany, and in France in the departments of Yonne, Cher, and Nièvre. The original colour of these ochres can be modified and varied into browns and reds of more or less intensity by calcination. The high heat expels the water of hydration from the iron oxide, changing it into red ferric oxide. The nature of the associated earth also influences the colour assumed by an ochre under calcination, aluminous ochres developing red and violet tints, while the calcareous varieties take brownish red and dark brown hues. The well-known ochre *Terra da Sienna* which in its raw state is a dull-coloured ochre, becomes when burnt a fine warm mahogany brown hue highly valued for artistic purposes. Yellow ochres are also artificially prepared—*Mars Yellow* being either pure hydrated ferric oxide or an intimate mixture of that substance with an argillaceous or calcareous earth, and such compounds by careful calcination can be transformed into *Mars Orange*, *Violet*, or *Red*, all highly important, stable, and reliable tints. The metal chromium owes its name to the intense coloration produced by the combination of its oxide, chromic acid, with various metals and alkaline earths. Several of these salts are soluble, but those which form pigments are insoluble compounds. The principal chrome pigments—the various shades of lemon and yellow chrome deepening to orange tints—are composed of the neutral chromate of lead, the difference of hue depending on the greater or smaller proportion of lead used in the preparation. The basic chromate of lead has a

deep orange colour passing into the minium-red-like hue of chrome red. *Strontia Chrome*, the chromate of strontium, is a pale lemon pigment of fine quality and permanence. With zinc, chromic acid forms two combinations, neutral and basic, both possessed of an intense yellow colour; and chromate of barium also furnishes a useful yellow colour. Lead itself, without chromium, is the basis of several valuable yellows. *Massicot*, the protoxide of lead, is a clear yellow pigment deficient in body. *Naples Yellow*, a colour highly esteemed by early artists, is an antimoniate of lead which in early times was obtained from native sources; and *Mineral Yellow* is an oxychloride of lead. The sulphide of cadmium forms the fine durable *Cadmium Yellow*, a colour now much appreciated for artistic use. The arsenical yellow, *Orpiment*, is now little used as a pigment, although formerly, under such names as *King's Yellow*, *Imperial Yellow*, and *Chinese Yellow*, it was held in high esteem by artists. *Aureolin*, a nitrate of potassium and cobalt, is a colour of recent origin which has come into high favour among artists. *Indian Yellow* is a colour of animal origin of no permanence, and *Gamboge* is a gum resin yielded by trees of the genus *Garcinia*, principally employed as a water colour. The yellow lakes are comparatively unimportant, but some, known, rather absurdly, as *Dutch*, *English*, or *Italian Pink*, are largely used in paper-staining.

**RED PIGMENTS** embrace two distinct series of substances—the reds of inorganic origin, and red lakes obtained from animal and vegetable colours. The principal commercial varieties are as follows:—rouge, Turkey red, and Indian red, red ferric oxide; Venetian red, ochreous ferric oxide; ochres, earths coloured by ferric oxide; vermilion and cinnabar, sulphide of mercury; antimony vermilion, red sulphide of antimony; Derby red, a form of chrome red; red lead or minium, red oxide of lead; chrome red, basic chromate of lead; realgar, bisulphide of arsenic; madder lake, alizarin and alumina; madder carmine, preparation of alizarin; carmine lake, cochineal red and alumina; carmine, preparation of cochineal; wood lakes, from various red dyewoods.

The principal mineral reds owe their colour to oxides of iron and to compounds of mercury. The reds due to iron are closely allied to the yellow ochres and other ferruginous pigments. As already explained in connexion with these yellows, tints passing through orange to deep purple reds are obtained by calcination of yellow hydrated ferric oxide, and in this way a great variety of ruddy and red tints are prepared. The proportion of ferric oxide in these compounds ranges from pure oxide to combinations in natural ochres containing not more than 2 or 3 per cent. of iron. *Rouge* or *Mars Red*, *Crocus*, *Indian Red*, and *Turkey Red* are all pure ferric oxide, varying in depth of tint from having undergone different degrees of calcination, or from being made from different artificial or natural sources. The other iron reds are all of the nature of ochres—some of them, such as *Venetian Red*, being artificial compounds. These reds form exceedingly useful durable colours which do not injuriously affect the tints with which they are associated. Of red colours from mercury, *Cinnabar* and *Vermilion* are the most important, the former being the native and the latter an artificial sulphide of mercury (see *MERCURY*, vol. xvi. p. 34). Vermilion is one of the most pure, brilliant, solid, and durable of all colours. Its beauty is largely affected by the smoothness of the powder to which it is reduced, and in this respect that obtained from China is of the highest excellence. Being a costly pigment, vermilion is freely adulterated with other reds, a fraud easily detected by the perfect volatility of the genuine substance. From mercury combined with iodine is prepared a pigment of unequalled vivacity and brilliance, *Iodine Scarlet*, but unfortunately as fugitive as it is bright, and consequently not available for work requiring permanence. The principal red colour from lead is *Minium* or *Red Lead*, a pigment of great antiquity obtained as a product of the oxidation of massicot, or by the calcination and oxidation of white lead. It is orange red in colour, of good opacity and body, but it has the fault of white lead and lead colours generally, blackening in contaminated air and injuring colours with which it comes in contact. By itself it is a valuable paint for first coating exposed iron surfaces to prevent their oxidation, and it is an excellent dryer, on which account it is much used in preparing boiled oil for painters. *Chrome Red*, a basic chromate of lead known also as *Persian* or *Derby Red*, is a brilliant pigment ranging in tone from orange to a deep vermilion hue. It is obtained by precipitating a solution of acetate of lead with bichromate of potash, with the addition of more or less of caustic potash or soda,—the proportion of the latter addition determining the depth of resultant tone. *Antimony Vermilion* is the red variety of the sulphide of antimony which, as found in nature (stibnite), is a dark grey body with metallic lustre. This, when fused and kept some time at a high heat and suddenly cooled, by allotropic modification becomes a fine vermilion red. The colour is artificially prepared by acting on solutions of the butter of antimony (antimony chloride) with hyposulphite of soda or lime. It is a colour of excellent purity and body as a water colour, but unfortunately it becomes brown by exposure. The lakes form a numerous and important class of red pigments. A lake is a combination of a colour of organic origin with a metallic oxide or salt,

commonly with alumina. Originally all lakes were red colours, the name being derived from the lac insect *Coccus lacca*, the colouring matter of which forms the lake now known as *Lac Lake*. But lakes of any colour or tint are now made. The most important lake pigment is *Madder Lake*, a compound of alumina and the tinctorial principle of madder root, *Rubia officinalis*, but now made with artificial alizarin. *Scarlet* or *Carmine Lake* has cochineal for its colour basis, and there are corresponding lakes from lac, kermes, &c. *Wood Lakes* coloured with several of the red dyewoods have little durability, but they are nevertheless largely used by paper-stainers. *Cerulean*, a colouring matter from cochineal, and *Madder Carmine* or *Field's Carmine*, from madder, are exceedingly brilliant colours; but the first of them is of a fugitive character.

**GREEN PIGMENTS** form an extensive group embracing two sections:—(1) simple greens, in which green is a primary inherent or natural colour; and (2) compound greens, made up of intimate mixtures of blue and yellow pigments. The latter class it is obvious are capable of indefinite modification by simply varying the proportions of the compound ingredients. The following list embraces the principal commercial greens:—*Brunswick green*, oxychloride of copper; *malachite green* or *mountain green*, hydrated carbonate of copper; *verdigris*, sub-acetate of copper; *verditer* or *Bremen green*, hydrated oxide of copper; *Scheele's green*, arsenite of copper; *Schweinfurt green*, mixed acetate and arsenite of copper; *emerald green*, a variety of *Schweinfurt green*; *mineral green*, mixed copper oxide and arsenite; *chrome green*, oxide of chromium; *Gaiguet green* or *veridian*, hydrated oxide of chromium; *Cassel green*, manganate of baryta; *cobalt green*, oxides of cobalt and zinc; *ultramarine green*, modified artificial ultramarine; *Veronese earth* or *terra verde*, a form of ochre; *green lakes*.

The greater proportion of these greens are copper compounds—the most brilliant of them containing also arsenic. They are all poisonous colours, the latter especially being dangerous poison; and there can be no doubt that their free use in wall papers, the colouring of toys, artificial flowers, &c., is frequently the source of dangerous disease and even death. *Brunswick Green*, the most important non-arsenical green, is an oxychloride of copper, but factitious *Brunswick greens* are not uncommon. *Scheele's Green*, the arsenite of copper, and *Schweinfurt Green*, mixed arsenite and acetate of copper, are very powerful and brilliant colours. These copper greens all blacken in foul gases and when mixed with oil, and thus, although they possess great body, they are much more useful to the paper-stainer than the painter. The sesquioxide of chromium both water-free and hydrated, prepared in various ways, forms important stable green colours which resist atmospheric influences; and chromium is further the basis of several other green colours, which, however, are not of importance. *Cobalt Green*, a mixed oxide of cobalt and zinc, discovered by the Swedish chemist *Linman*, is a valuable and durable but expensive colour. *Cassel Green*, called also *Rosenstiehl's Green*, is a fine innocuous pigment made by melting together sulphate of baryta and oxide of manganese, and carefully washing the resulting mass in water. *Verona Green* or *Terra Verde*, a natural celadon green highly valued by artists for permanence, is a mixed earthy body coloured by ferrous oxide, and *Ultramarine Green*, also a stable body, is an intermediate product of the manufacture of ultramarine blue.

**BROWN PIGMENTS.**—Many of the painters' browns are simply tints obtained by mixture. In the case of simple pigments the shades pass by fine gradations into yellows and reds, so that the limits of classification are not well defined. The following are generally classed as pure browns:—*umber*, silicate of iron and manganese; *brown ochres*, called *Mars brown*, iron brown, &c., native and artificial earths; *Vandyke brown* and *Cologne* or *Cassel brown*, peaty ochres; *purple brown*, ferric oxide; *Spanish brown* or *tiver*, a brown iron ochre; *bistre*, washed beechwood soot; *sepia*, secretion of cuttle-fish; *brown lake*; *asphaltum*, natural and artificial pitch.

*Iron and manganese*, separately or combined, earthy or pure, are the sources of the principal brown pigments. Some of them are intermediate products between yellow ochres and red ochres by calcination of the yellow, and, as they are ochreous in their nature, their colours may be heightened or otherwise modified by calcining. *Blue Ocher*, which properly is a hydrated silicate of manganese and iron, is brightened in colour by calcination into *Burnt Umber*. The finest water colour comes from the island of Cyprus, and is known as *Turkey umber*. Large quantities also of "English" umber are mined in Devonshire and Cornwall. Real *Vandyke Brown*, a very celebrated pigment, ought to be a kind of bituminous peaty earth of a fine rich semi-transparent colour, allied to which are *Cologne* and *Cassel Earth*. But under the name *Vandyke brown* pure ferric oxide and ferruginous earths of a clear brown hue are also sold. *Cassel Brown* is a peaty earth coloured by manganese, found at *Cassel* near *Cork*, Ireland, and is a valuable artists' colour, as is the *Bistre*, a brown washed from the soot of beechwood. *Sepia*, a brownish black ink, is a substance secreted by the cuttle-fish, which emits it to cloud the water for conceal-

**BLACK PIGMENTS** form a numerous class of bodies, though those in common use are easily enumerated. They appear in commerce principally under these names:—*vegetable black*, carbonized vegetable matter; *lamp black*, soot of oils and fats; *Indian ink*, preparation of lamp black; *ivory black*, carbonized ivory and bone; *bone black*, carbonized bone; *blue black*, washed wood charcoal; *charcoal black*, carbonized wood; *black wad*, a native oxide of manganese; *black lead*, a form of carbon; *tar*, from distillation of organic substances.

Most of these blacks owe their colour to carbon. From the charring of vegetable substances are prepared *Charcoal Black*, *Blue Black*, and *Vegetable Black*, but these take many names according as they are prepared from carbonized wood, twigs of the grape vine, peach and other fruit stones, cork, the lees of wine, &c. *Bone* and *Ivory Blacks* again are carbonized animal substances, principally bones, which when skilfully burned yield dense durable blacks. *Lamp Black* of the best quality is the soot deposited from the imperfect combustion of oils and fats, and the soots of resin and tar are also collected and used under this name. *Indian Ink* (see vol. xiii. p. 80) is a form under which lamp black of the finest quality occupies an important position among pigments. Of the other blacks *Tar* is the most important owing to its extensive use as a preservative and antiseptic coating.

Several pigments are prepared on account of special properties apart from the protective and decorative purposes for which ordinary paints are applied. Among such may be mentioned *Balmain's luminous paint*, a preparation in oil or water of certain of the phosphorescent sulphides. Objects coated with this material have the property of continuing to emit light in dark situations for some time after they have been exposed in daylight or to high artificial light. The luminous paint has been proposed for coating buoys, signals, public notice boards, clock and watch dials, playing balls, match boxes, &c., but it has not come into extensive use. Powdered asbestos has been introduced as a fire-proof paint for wood; but all common paints applied as distemper colour are equally fire-proof in the sense that they themselves are incombustible, and when they coat wood thickly they offer great resistance to an incipient fire, and even retard combustion under very high heat. Numerous anti-fouling compositions for the painting of ships' sides and bottoms and anti-corrosive, inoxidizable, damp-proof, and water-proof paints have been patented, some of which are in extensive use.

(J. P.A.)

**PIKE**, freshwater fishes generally distributed over the rivers and lakes of Europe, northern Asia, and North America, and forming a small family (*Esocidae*) of Soft-rayed Fishes. They are readily recognized by their elongate compressed body covered with small scales, a long head, long and spatulate snout, and very large mouth armed with strong and long teeth in the jaws and broad bands of smaller teeth on the palate and tongue. The teeth point backwards or can be depressed so as to offer no obstruction to any object entering the gape, but prevent its withdrawal in the opposite direction. The dorsal and anal fins are placed far back on the

European Pike (*Esoc lucius*).

tail, thus greatly increasing the propelling power of the fish, and, although pike are bad swimmers and lead rather a sedentary than a roving life, they are excelled by no other freshwater fish in rapidity of motion when, by a single stroke of the tail, they dash upon their prey or dart out of reach of danger. In the Old World one species only is known (*Esoc lucius*), which prefers lakes and sluggish reaches of rivers to strong currents or agitated waters. Its eastward range in northern Asia is not known; it extends into Lapland in the north and into central Italy

and the vicinity of Constantinople in the south, but is absent in the Italian Peninsula. The European species occurs also in North America, and is common in the eastern United States southwards to northern Ohio. But North America is tenanted by other species of pike besides, of which the larger is the Muskeonge or Mouskeonge of the Great Lakes (*Esox nubilus*); it commonly attains to the large size which is exceptionally recorded of *Esox lucius*. The other American pike are of smaller size, and generally named "Pickeral"; but opinions as to the distinction of the species differ widely among American ichthyologists. The European pike, like its brethren, is the most voracious of freshwater fishes; it probably exceeds the shark, to which it has been compared by many writers, in the relative quantity of food it consumes. Ponds would soon be depopulated but for its cannibal propensities, no pike being safe from another of its own kind large enough to swallow it. To the young of water-fowl pike are most destructive, and large specimens will seize rats or rabbits when they take to the water, and are said to attack even foxes and small dogs. Individuals of from forty to fifty pounds are not scarce, but captures of much larger ones are on record. Pike are wholesome food, and much esteemed in inland countries,—the smaller (of 20 to 24 inches in length) being preferred to the larger individuals. They are prolific, and not easily exterminated in a water in which they have been once allowed to spawn. According to season and climate they spawn in April or May, and sometimes as early as February.

**PIKE-PERCH** (*Lucioperca*), freshwater fishes closely allied to the perch, but with strong canine teeth standing between the smaller teeth of the jaws and palate. As indicated by the name, these fishes show some slight resemblance to the pike in their elongate body and head, and like that fish they are most dangerous enemies to other freshwater fishes. Their acclimatization therefore in waters intended for the culture of valuable food fishes is not advisable, though they compensate in some measure for their destructiveness by the excellent flavour of their flesh. In Europe two species occur, the more celebrated being the "Zander" of North Germany or "Schiel" of the Danube (*Lucioperca sandra*); strange to say, it is absent in the system of the Rhine. It prefers the quiet waters of large rivers and clear deep lakes, in which it reaches a weight of twenty-five or thirty pounds; it does not thrive in small and confined waters. The second European species (*Lucioperca wolgensis*) is limited to rivers in southern Russia and Hungary. In North America several pike-perches have been described, but in the most recent works only two are distinguished, viz., *Lucioperca americana*, which grows to a weight of twenty pounds, and the much smaller *Lucioperca canadensis*; both are abundant in the Canadian lakes and upper Mississippi, and the latter also in the Ohio.

**PILATE**,<sup>1</sup> **PONTIUS**, the fifth Roman procurator or "governor" (ἐπίτροπος, ἡγεμὼν) of Judæa, Samaria, and Idumæa, succeeded Valerius Gratus in 26 A.D. By rank he was a Roman eques, possibly of Samnite extraction; his official appointment he owed to the influence of Sejanus. His ordinary residence as procurator was at Cæsarea, the capital, but from time to time he visited Jerusalem, especially at the greater feasts, and on these occasions he had his seat in the magnificent palace of Herod the Great, hence called the *prætorium*. Apart from the supreme (to him, likely enough, most trivial) incident in

<sup>1</sup> *Id.*, *Pilatus*, either derived from *pilius*, and thus analogous with the surname *Tiberianus*, or a contraction of *pilatus*. The prefix was the badge of Romanized slaves, and if this etymology be accepted the name probably indicates that Pilate was a *libertus*, or the descendant of a *libertus*, of a member of the Summi Viri of the Pontifical

his life ("suffered under Pontius Pilate") the few facts that are known of him indicate a somewhat exceptional recklessness about awakening Jewish fanaticism, and unsuspiciousness as to the means used in quelling its manifestations. Not long after his appointment he allowed his soldiers to carry their eagles and other insignia to Jerusalem, and did not give way until an excited mob had stormed for five whole days and nights around his palace at Cæsarea. At a later date, in order to provide for the completion of his aqueduct for bringing water to the city from the "Pools of Solomon," he appropriated funds from the Corban or sacred treasury; but, profiting by his former experience, when this conduct was resented by the populace he caused some of his soldiers, disguised as Jewish citizens but armed with staves and daggers, to mingle in the crowd, when many casual spectators as well as rioters were trampled to death. For having hung up in Herod's palace certain gilt shields dedicated to Tiberius he was in vain remonstrated with by the Jews, but Tiberius, on being appealed to, ordered their transference to the temple of Augustus at Cæsarea. Of the circumstances under which he "mingled the blood" of certain Galileans "with their sacrifices" nothing is known; but his cruelty in causing a number of Samaritans to be attacked and massacred when assembled on Mount Gerizim led to a complaint being lodged with Vitellius the legate of Syria, and ultimately to his being deprived of his office early in 36 A.D. According to Eusebius (*H. E.*, ii. 7) he was banished to Vienne in Gaul, where various misfortunes caused him at last to commit suicide; the *Chronicle* of Malalas alleges, with less probability, that he was beheaded under Nero. Later legend (see, for example, the apocryphal *Mors Pilati* mentioned below) has a good deal more to say: his suicide was anticipatory of Caligula's sentence: the body was thrown into the Tiber and there caused disastrous tempests and floods; it afterwards produced similar effects in the Rhine at Vienne, and finally had to be consigned to a deep pool among the Alps. Local tradition points to a little tarn on Mount Pilatus near Lucerne; if anything is thrown into it the water is forthwith strangely agitated. The devil takes the body from the water on Good Fridays and sets it on a throne where it goes through the gesture of washing its hands. The fact that Pilate allowed Jesus to be crucified is by no means out of keeping with what we know of his indifference to the claims alike of justice and of mercy; that he obviously wished to spare him if this could be done without too much inconvenience to himself has, however, gained him in some quarters very generous recognition; thus Tertullian speaks of him as "jam pro sua conscientia Christianum," the Copts regard him as a martyr, and the Abyssinian Church has given him a place in its calendar (June 25). This view is reflected in the spurious *Paradosis Pilati*. Pilate's wife, known to tradition as Procla or Claudia Procla, is represented as having been a proselyte of the gate and a secret disciple of Jesus. She is commemorated as a saint in the Greek Church (Oct. 27).

There is a considerable body of apocryphal literature connected with the name of Pilate. The *Acta Pilati*, which forms part of the *Evangelium Nicodemum*, gives a copious account of the trial of Jesus, intermingled with legendary details of uncertain and very unequal value. It exists in a variety of texts, but in substance is supposed with most probability to date from about the middle of the 2nd century, and to be the work of a Jewish Christian, written for Jews. The *Epistola Pilati*, of which there are two differing forms, contains what purports to be Pilate's account to Tiberius of the resurrection of Jesus. The *Paradosis Pilati* relates his trial, condemnation, and execution at the emperor's command; Pilate appeals in prayer to Jesus, and, along with Procla his wife, is received as a true penitent into the number of the faithful. The *Mors Pilati* relates the circumstances of his suicide, the casting of his body into the Tiber, its removal to Vienne explained as "in Gehenna", and the final disposal of it as "in Lucania." For all

these apocryphal writings see Tischendorf's *Evangelia Apocrypha* (1863).

**PILCHARD** (*Clupea pilchardus*), a fish of the herring family (*Clupeidae*), abundant in the Mediterranean and on the Atlantic coasts of Europe, northwards to the British Channel. Sardine is another name for the same fish, which on the coast of Brittany and Normandy is also called *Célan* or *Célérén*. It is readily distinguished from the other European species of *Clupea* or herrings. The operculum is sculptured with ridges radiating and descending towards the suboperculum; the scales are large, about thirty along the lateral line, deciduous; the ventral fins are inserted below, or nearly below, the middle of the base of the dorsal fin; the dorsal fin has seventeen or eighteen, the anal from nineteen to twenty-one rays. A small blackish spot in the scapular region is very constant, and sometimes succeeded by other similar marks. There are no teeth on the palate; pyloric appendages exist in great numbers; the vertebrae number fifty-three. The pilchard is one of the most important fishes of the English Channel (see article **FISHERIES**, vol. ix. p. 253 sq.). It spawns at a distance from the shore, and, according to Couch, the spawn has been seen to extend several miles in length, and a mile or more in breadth floating on the surface of the sea, of the thickness of brown paper, and so tough as not to be readily torn in pieces. The spawning takes place at two periods of the year, viz., in April or May, and again in the early part of autumn; but it is not probable that the same individuals or shoals spawn twice in the same year. When commencing their migrations towards the land, the shoals consist of countless numbers, but they break up into smaller companies in close vicinity to the shore. Pilchards feed on minute crustaceans and other animalcules, and require two or three years before they attain their full size, which is about 10 inches in length. On the Pacific coasts of America, in New Zealand, and in Japan a pilchard occurs (*Clupea sagax*) which in its characters and habits is so similar to the European pilchard that its general utilization is deserving of attention, and there is every reason to believe that New Zealand could produce its own sardines and fumadoes. Immense shoals are reported to visit the east coast of Otago every year in February and March.

**PILES.** See **HÆMORRHOIDS**.

**PILGRIMAGE.** The word Pilgrimage (derived from the Latin *pereger*, i.e., *per-ager*, "one who traverses a region," through the intermediate forms *peregrinus*, *pellegrino*, *pelegrin*) denotes the act of journeying to some place esteemed sacred, for the purpose of discharging a religious obligation, or to obtain some supernatural assistance or benefit. The practice is common to many religions, and mounts back to prehistoric ages. It is ultimately traceable to the nature of tribal religion, in its early form of worship of a deity regarded as purely local in the sphere of his special influence. As community in religious acts was one of the principal ties between members of the same tribe, to the exclusion of outsiders, it would naturally become the rule, and then the duty, of the tribesmen to present themselves at recurrent intervals at the sanctuary of their tribal god. As they scattered away from their own settlement, and became travellers or sojourners amongst aliens, the belief that they were in some sense cut off from the protection of their tribal deity, and subjected to the influence of others in whose worship they had no share, would induce visits from a distance to the seat of their own religion, not merely for the purpose of keeping up their tribal relations, but to propitiate a power which perhaps could not hear supplications addressed from a distance, and would in any case be more ready to hear and answer prayers made in his own special shrine, attended with the appro-

priate rites performed by his own body of ministers. This latter consideration would operate even in the case of cults directed to the Sun-God, the Moon-Goddess, and the planetary bodies, which could hardly be regarded as localized within earthly boundaries, but might well be supposed more placable in shrines of exceptional splendour and sanctity, officered by a trained and numerous priesthood. And wherever it was believed that the deity not merely responded to prayer, but gave direct answers by omen or by oracle to inquirers, the frequentation of the prophetic seat would naturally increase. Further, as the political strength of any tribe grew, that would be attributed in a multitude of cases to the superior power of its tutelary god, or, where they worshipped the same deity as their neighbours, to some more acceptable mode of paying that worship, whence the custom would grow of making the principal temple of the most powerful tribe the meeting-place of the confederacy, as well for political deliberation as for the more directly religious purpose of reaffirming the common pact with sacrificial ceremonies. And if the strongest tribe passed from the stage of hegemony to that of sovereignty, whether by cession or by conquest, so becoming the nucleus of a nation or kingdom, the same feelings would operate yet more powerfully,—the subject tribes being either compelled to accept the gods of their conquerors, or voluntarily adopting them from a conviction of their superior might. Certain temples would in this wise become national from having been tribal, and in large empires, such as Egypt and Assyria, would collect worshippers from all the various peoples ruled under a common sceptre. The second stage in the genesis of special sanctuaries is peculiar to religions with a real or supposed historical basis, and takes the form of devotion towards localities which have been the scenes of important events in the lives of personages revered in the creeds of those religions. And the third stage, belonging to a much later period than either of the former, when self-consciousness had become more developed, is that where the aim of the pilgrims is primarily subjective, to stir up certain emotions in their own minds, through the means of the associations connected with special localities. But in each and all of these the fundamental underlying thought is the same, the localization of deity, the almost insuperable difficulty which the ideas of omniscience and omnipresence offer to undeveloped intellects.

It will be convenient, in tracing the history of pilgrimages, to begin with those which belong to the various forms of heathenism, ancient and modern, as pertaining, whatever be their actual date, to an earlier stage of mental evolution than the Jewish, Christian, and Mohammedan ones.

The first pilgrimages, then, of which we have any trustworthy knowledge, are those of ancient Egypt. The mythology of the Egyptians is even yet but imperfectly understood, but it is at any rate clear that, just as the votaries of Vishnu and of Siva keep apart in modern Hindustan, so the chief deities of the Egyptian pantheon had cults which were as often rival as complementary, and that the emulation of the competing temples took the form of bidding against each other for popular favour by the splendour of their chief yearly festivals. We are obliged to have recourse to Herodotus and Plutarch for information as to the general cycle of feasts nationally observed; for, although local calendars and rubrics of festivals have been discovered in several places, nothing cognate with Ovid's *Fasti* has yet been found in Egypt. Herodotus notices that, instead of having but one yearly national festival (*πανήγυρις*), the Egyptians had six, the principal of which was that of Artemis (i.e., Bast or Sekhet) at Bubastis, to which the pilgrims went in boats crowded with both sexes, playing on castanets and flutes, and singing to this accompaniment. They landed at every town along the

river to perform orgic dances, and at Bubastis itself offered great sacrifices, besides feasting copiously, in particular consuming vast quantities of grape-wine. He states the numbers assembling on this occasion, exclusive of children, to average 700,000. Next to this ranked the festival of Isis at Busiris, attended with ceremonies of mourning, most probably in memory of the sufferings of Osiris. Third in order was the feast of Athene (Neith) at Saïs, celebrated at night, with illuminations. Fourth was the festival of the Sun (Ra) at On or Heliopolis; fifth that at Buto in honour of Latona (Buto or Uat). These two were attended with simply sacrificial rites, and there were no symbolical ceremonies in addition. Last came the festival of Ares (Har-tash, the Hertosi of Cedrenus) at Papremis, at which there was a rough tussle, symbolizing war, between the temple-attendants and the pilgrims, in which lives were sometimes lost. There was another high festival, that of Apis at Memphis, not included by Herodotus in his list, perhaps because not of yearly recurrence, besides the much frequented oracle of Ammon at Thebes, whither it had been transferred from Meroe, its first seat in Egypt. And it is noticeable that there was no pilgrimage at all to the most sacred spot in Egypt, the island of Philæ, the burial-place of Osiris, because its very sanctity made it "tabu" to lay folk. The mysteries, in like manner, being rigidly confined to a few, did not form an occasion of pilgrimage.

As regards the great Mesopotamian empires, our knowledge does not yet enable us to say that pilgrimages entered into their religious system, though we may not unreasonably infer so from the size and wealth of several temples, notably those of Ishtar, from the Assyrian custom of imposing their own deities upon conquered nations, and from the example of one great religious assembly from all the provinces of the Babylonian empire, recorded in Daniel iii. There may, perhaps, be indirect proof of Babylonian pilgrimages in what Cyrus states in his cylinder-inscription, namely, that Nabonidus had offended the gods by transporting their images to Babylon, and thus, as it were, making them perform pilgrimage.

The ancient Zend creed of the Medes and Persians, having no temples for worship, had no pilgrimages; but in its later Mithraic form, the initiation of neophytes by the Magians into the mysteries, through a painful course of purgation (curiously resembling one prevalent in Ireland far within the present century), in a cavern or grotto at Babylon, necessitated a pilgrimage thither on the part of those who desired to become experts; and Lucian has left some account of its rules in his *Menippus*.<sup>1</sup>

Amongst the Phœnicians there are clear traces of at least two great pilgrimages in honour of Ashtoreth, one to Aphaca (probably the Aphek of Scripture), celebrated for a yearly miracle of a ball of fire appearing on the mountain summit, and thence falling into the sea. The obscene rites for which this temple was infamous led to its destruction by Constantine the Great (Euseb., *Vit. Const.*, iii. 56). The other great Ashtoreth pilgrimage was to Hierapolis in Syria, frequented by votaries from all the Semitic races except the Jews. Antioch was also a great centre of this cult, as also of that of Thammuz, but, strictly speaking, there is no proof of a Thammuz pilgrimage, nor of one in honour of Melkarth, though his worship was carried from Tyre, its chief seat, into all the Phœnician colonies, and the famous oracle of his temple at Gades drew crowds of inquirers annually. In Palestine proper, though the cults of Baal, Ashtoreth, Moloch, Dagon, and Beelzebub were widespread and persistent, and though the name Jericho

probably, and Ashtarothe-Karnaim certainly, point to a seat of moon-worship, as Bethshemesh does to one of sun-worship, there is no direct evidence of organized pilgrimages to these places.

In ancient Hellas there were four classes of religious Greek observance more or less cognate with pilgrimage, though not in any case identical therewith. First may be placed the consultation of oracles,—those of Apollo at Delphi, of Zeus at Dodona, of Trophonius at Lebadeia, and of Asclepius at Epidaurus (the last of which was resorted to also for the cure of disease) being the most famous and most frequented, while, outside Greece and its colonies, the oracle of the Libyan Ammon in the desert south of Cyrene was also in much esteem. Next come the four great national festivals and games, the Olympic, Pythian, Nemean, and Isthmian, attended by crowds from all Greek states, not only as attractive shows, but as religious ceremonies.<sup>2</sup> Thirdly may be named the more local or tribal festivals, such as the Panathenæa, the feast of the Charites at Orchomenus, that of Hera at Samos, of Aphrodite at Paphos, and of Artemis at Ephesus, which drew together many worshippers besides those who were specially bound to visit the shrines in question. But the closest parallel to the Christian theory of pilgrimage is found in the celebration of the Eleusinian mysteries (see MYSTERIES), the special likeness of which to pilgrimages of a later day lies in the notion of merit and spiritual benefit attached to initiation, to the belief that happiness in a future state of existence would be promoted, nay, insured, by admission to the ranks of the mystæ.

The Latin customs bear a certain superficial likeness to Roman. the Greek, in that local oracles, such as those of Faunus, of Albunea, of Fortuna, and of the Sibyls, were much frequented; there are traces of great tribal sanctuaries and gatherings, such as the worship of Jupiter Latiaris on the Alban Mount, of more narrowly restricted tribal cults, such as the Julian worship of Vejovis at Bovillæ and the Fabian sacrifice to Hercules on the Quirinal, and of at least two temples to which regular pilgrimages seem to have been made—those of Juno Sospita at Lanuvium, and of Vesta (perhaps of all the Penates also) at Lavinium. But, apart from racial and theosophic differences of belief, there was one factor at work in Italy which tended to bring about a wholly different character of popular religion from that which was evolved in Hellas—the overmastering centralization of Rome, and the practical identification of all solemn worship (apart from the rustic ceremonies in honour of minor and little-known deities) with the apotheosis of the Republic. Hence, after the chief seat of Roman worship was transferred from the Regia to the Capitol, pilgrimage proper disappeared, for the local gods of each newly absorbed city or state were added to the original triad of Roman gods, and to the other Sabine triad, moved from the Quirinal to the new sanctuary, and it becomes impossible to distinguish clearly between the purely political ceremonies performed in honour of gods viewed primarily as the tutelars of Rome and voluntary resort to the great temple for the personal cult of any particular deity enshrined there. One relic of the older custom seems to have survived till later times, namely, the pilgrimage of Roman women barefoot to the temple of Vesta in the Forum on June 9 every year.

No pilgrimages seem to have been usual in the Teutonic and Slavonic religions, though both had special temples and regarded as more sacred than the remainder, and in the case of the latter we know with tolerable accuracy that Kieff, Novgorod, Rethra in Mecklenburg, Karenz, Winneta

<sup>1</sup> This is probably the source of the Moslem legend of Harût and Marût, the fallen angels chained in a cavern at Babylon, who will teach magic to such as consult them in a prescribed manner.

<sup>2</sup> The Panhellenic festival at Ægina is omitted, as a mere factitious device of the emperor Hadrian, when classical paganism was dying, and not a real Greek custom.

and Julin (isle of Wollin), Stettin, and lastly Arkona in the isle of Rügen, succeeded one another as the chief seat of the worship of Perun, Lada, Bielbog, and other principal Slavic deities, and were necessarily attended by much larger bodies of worshippers than temples of less account, more thinly officered, and inferior in repute for the learning and prophetic powers of their priests.

**Mexican.** Directing our attention to an entirely different region of the world, we learn that in 1519, when Cortes entered Cholula in Mexico, he found it a great resort of pilgrims to the huge temple of Quetzalcoatl, then of unknown antiquity, as founded by a race earlier than the Aztecs, and built upon a colossal mound, vying in dimensions with the largest pyramids of Egypt. And what is yet more curious, besides this principal shrine, there were subsidiary tribal temples in the city, restricted to the uses of the several allied or kindred nations, who desired to have their own sanctuary in the holy city, precisely as churches of different nationalities are found in Jerusalem and in Rome to-day. And similarly in Peru, the great Temple of the Sun at Cuzco, with its encircling girdle of chapels dedicated to minor deities, was visited by pilgrims from all parts of the empire; nay, it was even regarded as a misfortune to fail in accomplishing the journey.

**Indian.** India, however, is above all others the land of pilgrimages, for it has observed them during a longer unbroken period than any other country of which we possess sufficient records, and for frequency and multitude it would be difficult to find any parallel. The most celebrated of them are those to the temple of Jagan-nāth at Puri in Orissa, Benares, Hurdwar, Ganga-Sagara, Gangotri, Jumnotri, Prayāga (Allahabad), Rāmésvara, Gaya in Behar, and Ayodhya or Oudh. Apart from the motives, common to all pilgrims, of acquiring religious merit or expiating sins, these Indian shrines are frequented for the performance of *śraddha* ceremonies in honour of deceased ancestors or as votive acts for the recovery of the sick, or, again, to carry the ashes of deceased kindred to be scattered in the waters of some sacred or purifying river. Every great river in India, with some lakes, tanks, and springs, is regarded as permeated with the divine essence, and as capable of cleansing from all sin. Hence the favourite resorts are river sources and confluences, while Benares, as situated on the Ganges itself, is the holiest spot in Hindustan. The other most frequented shrines are usually associated with the cults of Krishna, Siva, and Rāma. All these are exclusively connected with Brahman rites, for the entire extirpation of Buddhism from the Hindu peninsula has prevented any special sacredness from continuing to attach to the scenes of Gautama Buddha's life (though the Buddhists allege that the sanctity of Benares is due to its having been the residence of Buddha himself and the scene of his earliest preachings); and it is in Ceylon only that two Indo-Buddhist pilgrimages survive,—that of Adam's Peak, and the yet more popular one to the temple of Kandy, where the *Dalada Malagawa*, or tooth of Buddha, is an object of special veneration. For northern Buddhism the chief shrines are Lhasa in Tibet, the seat of the Dalai Lama, and Urga in northern Mongolia, the seat of the Tesho-Lama, Krashis Lunpo in Further Tibet, the seat of the Pantshien Lama. Before the Brahman revolution, which drove Buddhism out of India, pilgrimages to the chief scenes of Gautama Buddha's life were common; and notably Kapilavastu, his birthplace, Benares, where he began his mission, and Kasinagara, where he died, were much frequented, especially by Chinese converts. The narratives of some of these, Fa Hian, Hwai-Seng, and Sung-yun, and Hwen-Tsang, the most noteworthy of them all (see vol. xii. p. 418), who came to visit the holy places and to collect the sacred books, are still extant.

In China pilgrimages are made to several of the more sacred spots both by Buddhists and Confucianists. Wutai-shan in Shan-si is the chief resort of Buddhist pilgrims, and Tai-shan, the mountain sacred to Confucius, that of Confucianists (Williamson, *Journeys in North China*). In Japan both the older Shintō nature-worship and the newer Buddhist creed have their several sanctuaries and pilgrimages. The principal Shintō pilgrimages are those to Isé in the department of Watarai, and to the sacred mountain Fuji. There are two temples at Isé, ranking in sanctity first of all Shintō shrines, and the special seat of the worship of Ten-shōkō-daigin, the Sun-Goddess, from whom the Mikado is held to descend. Two great festivals are held yearly at Isé, in the sixth and twelfth months, and are known as *O-barai no matsuri*, "great purification feast," being held to effect the purifying of the whole nation from the sins of the previous half year. Tickets inscribed with the names of the gods of Isé, and especially that of the Sun-Goddess, are issued at the temples and their agencies (being formerly sold by hawkers corresponding to the pardoners of mediæval Europe), and are carefully preserved in the domestic shrine of Japanese houses, being supposed to avert all peril for six months, but requiring renewal at the end of that period. The pilgrims to Isé number many thousands yearly, and are known as they return by bundles of charms wrapped in oiled paper, and hanging from the neck by a string. The pilgrimage to Fuji takes place in summer, and the pilgrims go clad in white, and carrying bells. They ascend the mountain so as to reach the summit before sunrise, when they turn to the east, clap their hands, and chant a hymn to the Sun-Goddess. There are also many local Shintō pilgrimages of less note. Buddhism in Japan is broken up into several sects, having each of them their own pilgrimages; but the most frequented are those of the god Fudo at Narita and the sacred mountain of Oyama, each some 30 miles distant from Tokio. These both belong to the Shingou sect, the earliest introduced into Japan. The Hokke or Nichiren sect make pilgrimages to the monastery of Ikegami near Tokio, and to that at Mount Minobu, about 100 miles to the west, between which two shrines the relics of the founder are divided. Ninety miles north of Tokio are the shrines of Mount Nikko, also a great Buddhist pilgrimage, where the shoguns are buried, and where the founder of the Tokugawa dynasty is worshipped under the name of Gongen.

So much will suffice to have said concerning the various heathen pilgrimages, and we may now consider those of the Hebrew religion and its two derivatives, Islam and Christianity.

The legislation of the Pentateuch is precise in making Jewish resort to one central shrine a positive and fundamental precept, binding on the whole nation, obviously with the double object of cementing national unity and of guarding against the erection of local sanctuaries, which were liable to be diverted to idolatrous cults (see PENTATEUCH). Under the judges and the kings we find many traces of pilgrimage, not only to the sanctuary of the ark at Shiloh, and afterwards to Jerusalem, but to local high places, such as Ophrah, Mizpeh, Dan, Bethel, and Beersheba. In truth, it is not till the post-exilic period that the supremacy of one national sanctuary is assured (though a pilgrimage even after the destruction of the temple is recorded in Jeremiah xli. 5, showing that the mere site was held sacred), for the local devotion of the high places resisted all the efforts of the reforming party under Hezekiah and Josiah even in the kingdom of Judah itself. Since the final overthrow of the Jewish polity by Titus and Hadrian, no effort has been made either to establish a centre of sacrificial worship anywhere outside Palestine (as in the

teachers whose own acts had helped to propagate the opinion in question. Thus, only a few years after the letter above cited, urging Marcella to migrate to Bethlehem, St Jerome writes to Paulinus (393) pointing out that many of the most celebrated saints and ascetics had never visited the holy places, that heaven is just as open from Britain as from Jerusalem, and that the circumstances of life in Jerusalem itself were far from helpful to devotion. But his own abode at Bethlehem, the celebrity of the religious houses he founded and directed there, and the unlike tenor of other letters he wrote, entirely counteracted this advice. St Chrysostom at one time speaks of the needlessness of pilgrimage (*Hom. i. in Philem.*; *Hom. iii. and iv. ad pop. Antioch.*), and at another expresses his own wish to see the relics of St Paul at Rome (*Hom. xxxii. in Rom. ii. iii.*; *Hom. viii. in Eph. ii.*). So, too, St Augustine contributed powerfully to promote pilgrimages to the shrines of saints, by sending in 404 two clerical disputants to the shrine of St Felix of Nola, in the hope that some miracle would be worked there to decide the matter, though no such signs had been granted at the grave of any African saint (*Ep. lxxviii.*). And in another place he attests the working of many miracles by the relics of the protomartyr St Stephen in various African towns where portions of them had been shrined (*De Civ. Dei*, xxi. 8). Nevertheless, in yet a third place he appears to condemn this very temper as mere superstition, stating that, while he knows many professing Christians who are worshippers of tombs and pictures, "the church condemns them, and daily strives to correct them as evil children" (*De Mor. Eccl. Cath.*, xxxiv. 75, 76).

Here, too, example proved stronger than precept, and the only unqualified opposition to the popular tendency which issued from any quite unimpeachable source (for Vigilantius and Jovinian cannot be fairly cited) is the remarkable letter of St Gregory of Nyssa to a friend, on the subject of pilgrimages to Jerusalem, the heads of which are as under:—there is no divine precept for the usage; the moral dangers of the journey, from bad companions and from the quality of the inns, are great, especially to women, and above all to nuns; the immorality and irreligion of Jerusalem itself are gross and notorious. True, he had gone thither himself, but it was on public ecclesiastical business, connected with the Arabian Church, and he had travelled in a public vehicle with a company of monks. He did not find his faith stimulated or improved in any way by a sight of the scenes of the gospel history, and he recommends others to stay at home, assuring them that no spiritual benefit is lost by so doing, and no spiritual gain acquired by visiting the most sacred places without inward amendment (*Epist. ii.*). The authenticity of this epistle has been challenged, but on no sufficient grounds.

What makes the devotion to the tombs of saints such a powerful factor in ecclesiastical history is that, after the Holy Sepulchre itself, no grave had such a hold on Christian imagination as that where the bodies of the two chief apostles, St Peter and St Paul, were held to rest in Rome. And consequently, as the division of the empire lessened the intercourse between East and West, as the decay of the old lines of communication made travelling more difficult, and as the advance of Mohammedanism in Syria and Palestine made it more dangerous also in that direction, Rome gradually supplanted Jerusalem to a great degree in the West as the goal of pilgrimage, and the enthusiasm of the visitors did much to consolidate the papal monarchy over Latin Christendom. So markedly did this new influence prevail that it has left its trace in more than one European language. The Low Latin *romeria*, *romipè*, for a pilgrim anywhither, *romeria*, *romi-*

*petagium* for the actual pilgrimage, the obsolete French *romieu*, *romipète*, *romivage*, the still current Spanish *romero*, *romeria*, and Portuguese *romeiro*, *romaria*, the Italian forename *Romeo*, and the English *romare* (*Piers Plowman*) attest the celebrity and popularity of this pilgrimage, into which soon entered such further ideas as the desirability of confessing sins to the pope personally and obtaining absolution from him, the reference of private cases to papal arbitration on the part of bishops and other ecclesiastical judges, and the injunction of the journey as in itself a penance, a notion prevalent in the Gallic churches as early as the close of the 5th century (Cæsar. Arelat., *Hom. iii.*). Nowhere was the pilgrimage to Rome more popular than in Saxon England, and amongst the crowds of penitents who made the journey were four kings, Ceadwalla, Ine, Coinred, and Offa, all of whom died in Rome, two of them as monks (Beda, *H.E.*, v. 7, 19). There were not wanting efforts to check the movement. Apart from the theological objections raised by Claudius of Turin, there is a letter extant from Boniface of Mainz, an Englishman born, to Cuthbert, archbishop of Canterbury, written about 743, begging him to get a canon enacted to forbid the pilgrimage to Rome, especially to nuns, on the ground of the moral perils of the road, stating that no city of France, Lombardy, or Italy was without Englishwomen leading depraved lives, whose virtue had fallen during pilgrimage. And the council of Chalons, in 813, enacted a canon to check pilgrimages both to Rome and to the shrine of St Martin at Tours (then the most famous sanctuary in France), on the ground of serious abuses on the part of both clergy and laity; and the council of Seligenstadt made a like effort in 1022. But even the robber barons who looked on pilgrims as their natural prey could not arrest the movement (which was specially stimulated, as we learn from Radulphus Glaber, in 999 and 1000 by the belief that the end of the world was at hand), and the Roman pilgrimage reached its height in the Middle Ages through the institution of the Jubilee, or plenary indulgence to pilgrims, by Boniface VIII. in 1300, when 200,000 are said to have availed themselves of it, and smaller but still considerable numbers on its various repetitions at irregular intervals since. The pilgrimage to Jerusalem received fresh stimulus in the 9th century by the first occurrence of the alleged miracle of the heavenly fire on Easter Eve at the Holy Sepulchre, and continued to be frequented till checked by the fanaticism of the caliph Hakem-Biamrillah about 1018, and more severely and permanently by the Seljukian Turks on their conquest of Syria, which occasioned those armed pilgrimages, the crusades, to whose history this branch of the subject thenceforward belongs. Meanwhile, a third class of sanctuaries had been steadily coming into notice and popularity, consisting neither of the seats of great historical events nor of the ascertained resting-places of eminent saints. These were the purely legendary shrines, the sites of some alleged vision, of the supernatural discovery of hidden relics, or of the presence of a wonder-working image or picture. One of the earliest and most famous of these was that of Compostella, where the relics of St James the Great were said to be discovered in 816, and, after being again hidden for many centuries, to have been discovered afresh in 1884. This was one of those most frequented by English pilgrims, no fewer than 2460 licences being granted for the journey in the one year 1434 (Rymer, *Fæd.*, xi.).<sup>1</sup>

<sup>1</sup> This concourse of English pilgrims was soon looked on in France as politically dangerous, so that in the 14th century, when Pedro the Cruel was dethroned by Henry of Trastámara, the latter was compelled by his allies to refuse entrance into Spain to all pilgrims who had not licence of transit from the king of France. This kind of jealousy
